

## Supplementary Information

- **Protein ID/QT Methods**
- **Table S1.** Proteins found de-regulated in 6 dpf zebrafish larvae exposed to 5 µg/L of MeHg.
- **Table S2.** Proteins found de-regulated in 6dpf zebrafish larvae exposed to 25 µg/L of MeHg.
- **Table S3.** References supporting the organ-specific location of proteins found deregulated upon 25 µg/L MeHg exposure based on in-situ hybridation studies.
- **Figure S1.** Number of identified proteins in the different SCX and IEF fractions in both biological replicates (ZFA and ZFB).
- **Figure S2.** Top network generated by IPA. The associated network functions include cellular assembly and organization; cellular function and maintenance; and cellular movement.
- **Figure S3.** Differences in the size of the swim bladder of control (A) and ZF exposed to 5 (B) and 25 µg/L (C) of MeHg.
- **Figure S4.** Morphological and histological analyses of the eye of control (A, D) and ZF exposed to 5 (B, E) and 25 µg/L (C, F) of MeHg .

## Protein ID/QT Methods

Protein identification and relative quantification were performed with the ProteinPilot™ software (version 3.0; ABSCIEX) using the Paragon™ algorithm as the search engine. Each MS/MS spectrum was searched against the NCBI *Danio rerio* database (released on 08/31/2010) containing 27587 entries, downloaded from [ftp://ftp.ncbi.nih.gov/genomes/D\\_rerio/protein/](ftp://ftp.ncbi.nih.gov/genomes/D_rerio/protein/). The target plus reversed protein database contained 55174 proteins. The search parameters allowed for cysteine modification by methyl methane-thiosulfonate and the 220 biological modifications programmed in the algorithm (i.e., phosphorylations, amidations, semitryptic fragments, etc.). The detected protein threshold (Unused ProtScore (conf)) in the software was set to 1.3 to achieve 95% confidence and identified proteins were grouped by the ProGroup algorithm (Applied Biosystems) to minimize redundancy. The bias correction option was executed so the ratios of each analysis were automatically normalized.

To compare the performance of each separation technique at the protein identification level, the complete set of raw data files of each approach was analysed independently using ProteinPilot, which includes Paragon and ProGroup algorithms). A comparison between the gi Accession numbers of identified proteins from SCX and IEF approaches was carried out using Venn diagrams (*Oliveros, J.C. (2007) VENNY. An interactive tool for comparing lists with Venn Diagrams. <http://bioinfoqp.cnb.csic.es/tools/venny/index.html>*).

The peptide and protein selection criteria for relative quantitation were performed as follows. Proteins were identified on the basis of having at least two peptides with an ion score above 95% confidence. Only peptides unique for a given protein were considered for relative quantitation, excluding those

common to other isoforms or proteins of the same family. Among the identified peptides, some of them were excluded from the quantitative analysis for one of the following reasons: i) the peaks corresponding to the iTRAQ labels were not detected, ii) they were identified with low ID confidence ( $< 1.0\%$ ), iii) because of shared MS/MS spectra, when either the same peptide sequence is claimed by more than one protein or when more than one peptide is fragmented at the same time, iv) the peptide ratios where the sum of the signal-to-noise ratio for all of the peak pairs was  $< 9$ , v) peptides with a combined feature probability less than 30%, including semi-tryptic peptides, peptides missing an iTRAQ reagent label, peptides with low probability modifications and peptides with large delta masses. The protein sequence coverage (95%) was estimated for specific proteins by the percentage of matching amino acids from the identified peptides having confidence greater than or equal to 95% divided by the total number of amino acids in the sequence.

Two quantitative estimates provided for each protein by the ProteinPilot<sup>TM</sup> were utilized: the fold change ratios of differential expression between labelled protein extracts and the  $P$  value, representing the probability that the observed ratio is different to 1 by chance. To estimate and minimize the false discovery rate (FDR), defined as the percentage of decoy proteins identified against the total protein identification, a target-decoy search strategy was followed using a protein sequence database that combines forward and reverse amino acid orientation of every NCBI zebrafish protein sequence. The estimated FDR was less than 0.3% in both biological replicates, indicating high reliability in the proteins identified.

The results were then exported into Excel for manual data interpretation. Although relative quantification and statistical analysis were provided by the ProteinPilot 3.0 software, an additional 1.5-fold change cutoff for all iTRAQ ratios (ratio  $<0.67$  or  $>1.5$ ) was selected to classify proteins as up- or down-regulated. Proteins with iTRAQ ratios below the low range (0.67) were considered to be under-expressed, while those above the high range (1.5) were considered overexpressed. The average ratio provided by ProteinPilot includes correction from experimental bias and is inversely weighted by the % Error on each distinct peptide. For further information about how the average ratio is calculated, please refer to the manual.

**Table S1.** Proteins found de-regulated in 6 dpf zebrafish larvae exposed to 5 µg/L of MeHg.
