## Chemical procedures and spectroscopic data for starting materials and intermediate products

### General procedure for the synthesis of monoesters **18** and **21**

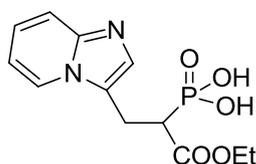

A one-neck flask equipped with a magnetic stir bar was purged with argon and then appropriate triester (1 eq) was placed. After cooling to  $-5^{\circ}\text{C}$ , bromotrimethylsilane (0.8 ml/1 mmol of substrate, 6 eq) was slowly added and resulting mixture was stirred for 4 hours (in case of triester bearing imidazo[1,2-*a*]pyridine ring addition of DCM (1 ml/1 mmol of substrate) was required after 1 hour). Then the volatile material was evaporated under reduced pressure and EtOH (20 ml/1 mmol of substrate),  $\text{H}_2\text{O}$  (2 drops/1 mmol of substrate) were added and stirring was continued for 2 hours. After careful evaporation of the solvent, obtained semi-solid was used in the next step without further purification. In case of synthesis compound **21** reaction could be carried out in presence of TEA (1 eq) used as scavenger of HBr formed in the reaction or present in BTMS.

## Synthesis of compound 39

To synthesize compounds with acyloxyalkyl moieties (**3**) we tried also an approach utilizing dimethyl ester **38** as starting material. Such approach was successfully applied in synthesis of allylphosphonates prodrugs, where introduction of acyloxyalkyl residue to phosphonic group was achieved on the action of pivaloxyl chloride in the presence of sodium iodide.\* Applying such conditions have led to formation of product **39** (Scheme 2) characterized by upfield chemical shift in  $^{31}\text{P}$  NMR (~19.5 ppm) compared with the expected products **3** (~21.5 ppm). Also, in  $^1\text{H}$  NMR we observed one additional methylene group, in the area of 6.5 ppm, and in aromatic area, signals of all protons were shifted downfield (0.5-1 ppm). These data suggested formation of compound containing three POM groups **39**, two in the phosphonate residue and one attached to nitrogen in pyridine ring which was confirmed by NMR and MS. Since quaternization of pyridine nitrogen turned out to be faster than trans-esterification of phosphonate group, we

protected nitrogen atom by forming pyridine oxide. This approach failed and *N*-alkylation reaction could not be suppressed.

**Scheme S1.** Formation of quaternized pyridine analog: Reagents and conditions: (a) NaI (2 eq), ACN, 80°C, 3 h.

Triester **38** (0.1 g, 0.35 mmol) was dissolved in ACN (1 ml). Then NaI (0.15 g, 1.05 mmol, 3 eq) and POM-Cl (0.16 g, 0.15 ml, 1.05 mmol, 3 eq) were added and the resulting mixture was stirred for 3 hours in 80°C. Solvent was evaporated under reduced pressure and residue was dissolved in H<sub>2</sub>O (1 ml). After pH adjustment to 9 using Na<sub>2</sub>CO<sub>2</sub> (s), mixture was extracted with Et<sub>2</sub>O (3x4 ml). Organic layer was dried over anhydrous MgSO<sub>4</sub>, solvent was evaporated and residue was subjected to column chromatography using DCM:MeOH (25:1) system as eluent to give 96 mg (45 %) of product as yellow oil.

\***A.** Waters Acquity UPLC equipped with autosampler and coupled with mass spectrometer Waters Micromass LCT Premier XE, column Waters UPLC BEH C<sub>18</sub> (1.7 $\mu$ m, 50mm x 2.1mm). The UV detector was operated at 261 and 280 nm for **1b** and **2b** derivatives respectively. Eluents: A: 10 mM ammonium acetate, pH 7; B: methanol/10 mM ammonium acetate, pH 7 (90/10, v/v). Gradient: from 0 to 0.25 min: 90 % of A, from 3.75 to 4.00 min: 1 % of A at a flow rate of 0.3 mL/min.

**B.** Dionex Ultimate 3000 – LC system equipped with autosampler, column compartment, diode array detector and column Thermo Hypersil Gold (1.9  $\mu$ m, 2.1 x 50 mm). The detection was performed at a wavelength of 263 nm or 281 nm for **1b** and **2b** derivatives respectively. Eluents: A: methanol/water/formic acid (5/94.9/0.1, v/v/v); B: methanol/water/formic acid (95/4.9/0.1, v/v/v). Gradient: 0-100% in 15.2 min of B at a flow rate of 0.2 mL/min.
