Supplementary calculation for mole balance

## Carbon balance (For Au/CeZrO<sub>x</sub> catalyst at 375 °C)

 $CH_3OH$  moles IN = 0.00021485 moles/min

 $O_2$  moles IN = 0.000112303 moles/min

Feed ratio  $O_2:CH_3OH = 0.491$ 

Reactor outlet mole balance:

Exit flow rate 50 cc/min measured by bubble flow meter.

The product mole flow rate were calculated using GC response factor to evaluate the mole fraction for each element then multiplied by the total exit flow rate. Ideal gas rate law was assumed in all the calculations.

		0.000010000 1 / :							
$CH_3OH$ moles out =		0.000018009 moles/min							
$O_2$ moles out =		0.0 moles/min							
H <sub>2</sub> moles out	=	0.00029727 moles/min							
CO moles out	=	0.0000479 moles/min							
CO <sub>2</sub> moles out	=	0.000146257 moles/min							
		Reacted moles of CH <sub>3</sub> O	H						
Conversion of $CH_3OH = \frac{Reacted moles of CH_3OH}{inlet moles of CH_3OH} x 100\% = 91.62\%$									
Selectivity of H <sub>2</sub>									
moles of $H_2$ produced 0.00029727									
$= \frac{moles \ of \ H_2 \ produced}{moles \ of \ CH_3 OH \ reacted \ x \ 2} x 100\% = \frac{0.00029727}{(0.00021485 - 0.000018009)x2}$									
x  100% = 75.5%									
Carbon balance:									
<i>Moles of carbon IN = 0.00021485 moles/min</i>									
Moles of carbon out = 0.000018009+0.0000479+0.000146257									
= 0.000212166 moles/min									
		l f	0.000212166						

 $Carbon \ balace = \frac{outlet \ moles \ of \ carbon}{Inlet \ moles \ of \ carbon} x \ 100\% = \frac{0.000212166}{0.00021485} \ x100\% = 98.7\%$ 

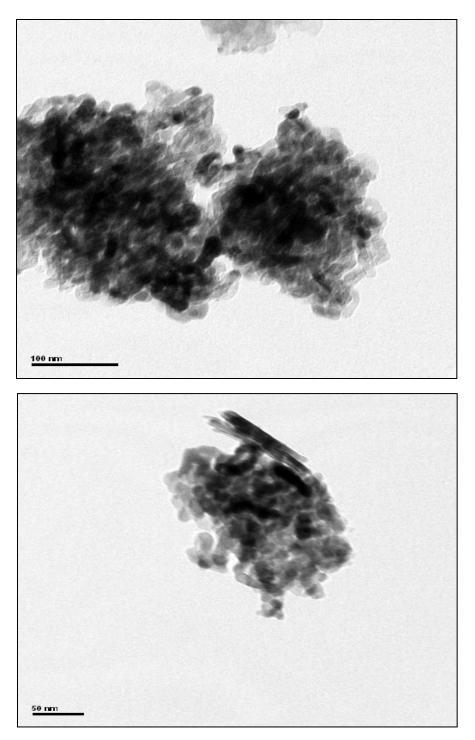

Figure S1. TEM (235KX magnification) show that the powders essentially comprised of finely divided material in the form of clusters. Each cluster consists of entangled tape-like structures, each strand being 5-10nm in width. Hence the overall material is very porous.
