## Experimental Section

The preparation of CuMn<sub>2</sub>O<sub>4</sub>, CoMn<sub>2</sub>O<sub>4</sub>, NiMn<sub>2</sub>O<sub>4</sub>, NiCo<sub>2</sub>O<sub>4</sub>, FeCo<sub>2</sub>O<sub>4</sub> and CuCo<sub>2</sub>O<sub>4</sub> nanostructures involves two steps. Taking CuCo<sub>2</sub>O<sub>4</sub> as an example, 0.4 mmol Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O, 0.8 mmol Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, 1.44 mmol citric acid (CA) and 1.2 g polyacrylonitrile were dissolved in 19 mL of dimethylformamide solvent. The applied voltage, feeding rate, and distance between the stainless steel needle and collector were 18 kV, 1.0 mL/h and 22 cm, respectively. Then, the obtained PAN@CuCo<sub>2</sub>O<sub>4</sub> precursor was calcined at 400 °C for 2 h. By simply changing the heating rate from 0.5 to 10 °C/min, the nanostructures of CuCo<sub>2</sub>O<sub>4</sub> can be tuned from hollow tube to 1D solid structure. The obtained catalysts were labeled as CuCo<sub>2</sub>O<sub>4</sub>-0.5 (0.5 °C/min), CuCo<sub>2</sub>O<sub>4</sub> (1 °C/min), CuCo<sub>2</sub>O<sub>4</sub>-3 (3 °C/min), CuCo<sub>2</sub>O<sub>4</sub>-5 (5 °C/min) and CuCo<sub>2</sub>O<sub>4</sub>-solid (10 °C/min), respectively. The synthesis process of other mixed metal oxides with hollow tubular structure or 1D solid nanowire, such as NiCo<sub>2</sub>O<sub>4</sub>, FeCo<sub>2</sub>O<sub>4</sub>, CuMn<sub>2</sub>O<sub>4</sub>, CoMn<sub>2</sub>O<sub>4</sub> and NiMn<sub>2</sub>O<sub>4</sub> is similar to that of CuCo<sub>2</sub>O<sub>4</sub> except for using different raw materials of nitrate.

## Catalytic activity tests

SCR activity measurement was performed in a fixed-bed stainless steel reactor (inner diameter = 8 mm). Before each test, 0.2 g of sample was pretreated by 5 vol% H<sub>2</sub>/Ar at 400 °C for 2 h. After cooled to test temperature, the feed gas (335 ppm NO, 340 ppm NH<sub>3</sub> and 2 vol% O<sub>2</sub> balanced with Ar) was introduced using mass-flow

controllers, and the total flow rate was kept at 600 mL/min. and the gas hourly space velocity (GHSV) is 150,000 h<sup>-1</sup>. Besides, hollow tubular CuCo<sub>2</sub>O<sub>4</sub> was also tested in a wide GHSV including 200,000, 250,000, 300,000 and 400,000h<sup>-1</sup>). Resistance against H<sub>2</sub>O was examined through introducing 7 vol% H<sub>2</sub>O into feed gas at 250 °C. SO<sub>2</sub> poisoning experiment was carried out by exposing samples to feed gas containing additional 100 ppm SO<sub>2</sub> at 250 °C. Stability tests of hollow tubular CuCo<sub>2</sub>O<sub>4</sub> and CuCo<sub>2</sub>O<sub>4</sub>-solid were performed at 400 °C for 30 h. The outlet NO<sub>x</sub> concentration was monitored by an on-line chemiluminescence NO-NO<sub>2</sub>-NO<sub>x</sub> analyzer (Model 42i-HL, Thermo Scientific). The outlet N<sub>2</sub>O was analyzed using an FTIR spectrometer (Nicolet Nexus 6700) with a heated, multiple-path gas cell. NO<sub>x</sub> conversion under steady-state conditions for 1 h was calculated according to the following equation.

$$\text{NO}_x \text{ conversion (\%)} = (\text{NO}_{x \text{ inlet}} - \text{NO}_{x \text{ outlet}}) / \text{NO}_{x \text{ inlet}} \times 100\%$$

Transient response method (TRM) of hollow tubular CuCo<sub>2</sub>O<sub>4</sub> was carried out at 150 °C according to literature methods [1, 2]. A 0.1 g sample was firstly pretreated in air flow (30 mL/min) at 400 °C for 0.5 h. After cooling to 150 °C, 250 ppm NO was introduced and the reactor was maintained at steady state for 30 min, then a feed gas of 250 ppm NO, 1 vol% O<sub>2</sub> and 250 ppm NH<sub>3</sub> balanced by Ar were introduced in the next step. The outlet gas concentrations were continuously monitored by a mass spectrometer and UV analyzer.

### ***Catalyst characterization***

X-ray diffraction (XRD) patterns were recorded on a RIGAKU-Miniflex II X-ray diffractometer with Cu K<sub>α</sub> radiation (λ = 1.5406 Å). N<sub>2</sub> physisorption measurement was performed on an ASAP 2020 apparatus, the sample was degassed in vacuo at 180 °C at least 6 h before the measurement. Field Emission Scanning Electron Microscope (FESEM) was performed on JSM6700-F. Transmission Electron Microscope (TEM) and high-resolution transmission electron microscopy (HRTEM) measurements were carried out on a JEM-2010 microscope operating at 200 kV in the mode of bright field. X-ray photoelectron spectroscopy (XPS) analysis was performed on Physical Electronics Quantum 2000, equipped with a monochromatic Al-K<sub>α</sub> source (K<sub>α</sub> = 1,486.6 eV) as a radiation source at 300 W under UHV. Catalyst charging during the measurement was compensated by an electron flood gun. High-resolution spectra were acquired with a pass energy of 20 eV. The area of analysis was 700 × 300 μm in size, and each sample was analyzed at a 90° takeoff angle with a depth of 3-4 nm.

H<sub>2</sub> temperature-programmed reduction (H<sub>2</sub>-TPR) was performed on AutoChem II 2920 equipped with a TCD detector, in which the sample was pretreated under air flow (30 mL/min) at 400 °C for 0.5 h, followed by purging with Ar (30 mL/min) at the same temperature for 0.5 h, and then cooled down to 50 °C. H<sub>2</sub>-TPR was started from 50 to 800 °C under 10 vol% H<sub>2</sub>/Ar.

Oxygen temperature-programmed desorption (O<sub>2</sub>-TPD) was conducted on an AutoChem 2920 equipped with a TCD detector. The adsorption of O<sub>2</sub> was performed in a 4% O<sub>2</sub>/He gas flow for 1 h at 150 °C. Afterward, the sample was heated to 900 °C at a heating rate of 1 °C/min in a pure He gas flow. O<sub>2</sub>-TPD quadruple mass spectroscopy (Q-MS) was used to analyze evolving gases. The signals for O<sub>2</sub> (m/z = 32), H<sub>2</sub>O (m/z= 18), and CO<sub>2</sub> (m/z=44) were monitored by using a QIC20 bench top gas analysis system connected to an AutoChemII 2920 outlet.

Ammonia temperature-programmed desorption (NH<sub>3</sub>-TPD) was also conducted on the AutoChem 2920 equipped with a TCD detector. 0.1 g of sample was pretreated in Ar at 350 °C for 1h. After cooled to 50 °C, the sample was exposed to 1.0 vol% NH<sub>3</sub>/Ar for 0.5 h, followed by a Ar purge at 100 °C to remove physisorbed ammonia. Finally, NH<sub>3</sub>-TPD was measured from 50 to 1000 °C.

*In situ* diffuse reflection infrared Fourier transform spectroscopy (DRIFTS) was recorded on a Nicolet Nexus FT-IR spectrometer in the range of 650-4000 cm<sup>-1</sup> with 32 scans at a resolution of 4 cm<sup>-1</sup>. Prior to each experiment, the sample was pretreated at 350 °C for 0.5 h in a gas flow of N<sub>2</sub> to remove any adsorbed impurities, and then cooled down to 50 °C. The background spectrum was collected under N<sub>2</sub> and automatically subtracted from the sample spectra. Afterward, NH<sub>3</sub> (500 ppm balanced with Ar) was introduced to the cell in a flow rate of 30 mL/min at 100°C for 1 h to ensure complete absorption saturation. After physisorbed ammonia was removed by flushing wafer with N<sub>2</sub> at 100 °C for 3 h, DRIFTS spectra were recorded at 50-350 °C. After NH<sub>3</sub> adsorption, the catalyst was pretreated at 200 °C under an N<sub>2</sub> flow with 20 mL/min for 1 h, subsequently 500 ppm of NO + 5 vol % O<sub>2</sub>/Ar (20 mL/min) were introduced to investigate the reactivity of pre-adsorbed NH<sub>3</sub> with NO + O<sub>2</sub> species.

All spin-polarized DFT calculations were carried out using the Vienna ab Initio Simulation Program (VASP) with the gradient-corrected PW91 exchange-correction function. For valence electrons, a tight convergence of the plane-wave expansion was obtained with a kinetic energy cutoff of 500 eV, and the ionic cores were described

with the projector augmented-wave (PAW) method. The Brillouin zone of the Monkhorst-Pack grid was set at  $2 \times 2 \times 1$ . For energy calculation, the electronic energy was converged to  $10^{-5}$  eV, and the positions of the atoms were allowed to relax until all forces were smaller than  $0.02$  eV/Å. The  $O_2$  adsorption ability is defined by using adsorption energy term ( $E_{ads}$ ), which is calculated according to  $E_{ads} = E_{(surface+gas)} - E_{surface} - E_{gas}$ .  $E_{(surface+gas)}$ ,  $E_{surface}$  and  $E_{gas}$  are the total energy of the optimized adsorbate surface system, energy of the naked surface and energy of a gas molecule, respectively. The energy of oxygen vacancy formation ( $E_v$ ) was calculated according to  $E_v = E_{oxygen\ vacancy\ system} + 1/2E_{O_2} - E_{full\ system}$ , this formula assumes that the oxygen atoms leaving the surface combine to form the oxygen molecule.  $E_{oxygen\ vacancy\ system}$ ,  $E_{O_2}$  and  $E_{full\ system}$  are the energy of the oxygen vacancy system, energy of an oxygen molecule, and energy of the full system, respectively.

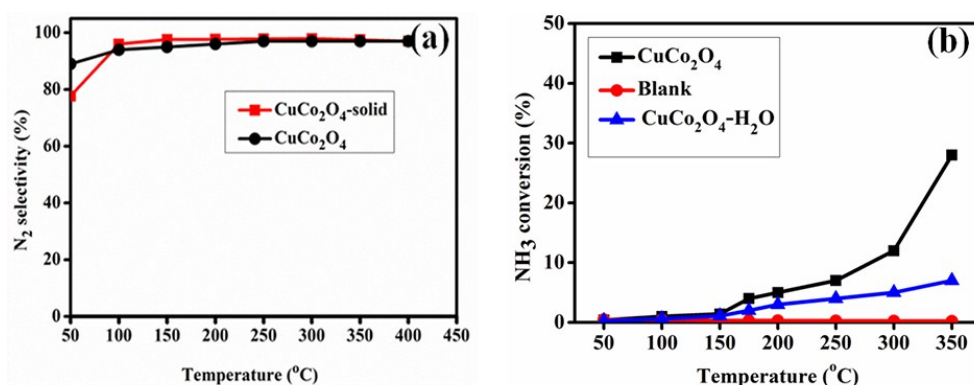

**Figure S1** Synthetic route of  $CuCo_2O_4$  with hollow tubular and solid 1D nanostructure.

**Figure S2** HRTEM images of (a)  $CuCo_2O_{4-0.5}$ ; (b, f, g, h, i, j)  $CuCo_2O_4$  ( $CuCo_2O_{4-1}$ ); (c)  $CuCo_2O_{4-3}$ ; (d)  $CuCo_2O_{4-5}$  and (e, k, l, m, n, o)  $CuCo_2O_4$ -solid ( $CuCo_2O_{4-10}$ ).

HRTEM images {Figure S2 (b, f, g, h, i, j)} show that the spacing distances between two fringes in hollow tubular  $\text{CuCo}_2\text{O}_4$  ( $\text{CuCo}_2\text{O}_4$ -1) are 0.282-0.289 and 0.460 nm, matching with (220) and (111) planes, respectively. For  $\text{CuCo}_2\text{O}_4$ -solid {Figure S2 (e, k, l, m, n, o)}, the lattice spacing of 0.242-0.248 and 0.472 nm correspond to (311) and (111) crystal planes, respectively, while the lattice spacing of 0.230 nm corresponds to (222) plane.

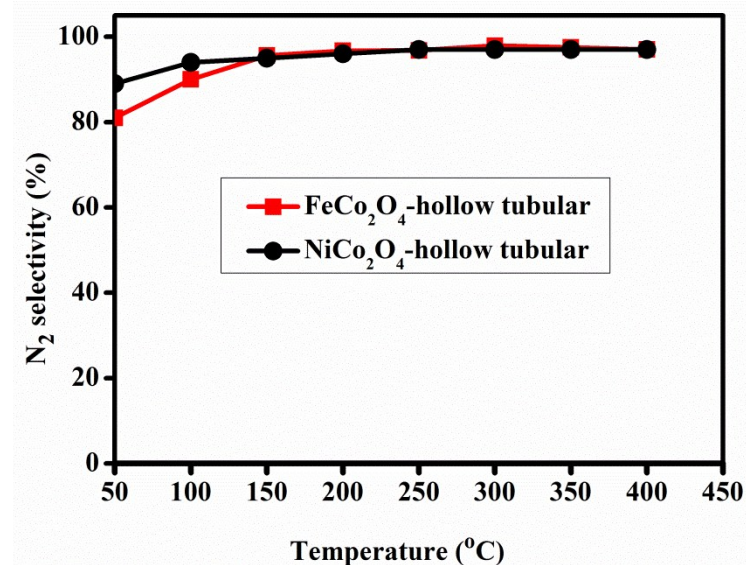

Figure S16 N<sub>2</sub> selectivity of FeCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub> with hollow tubular structures.

**Figure S17** O<sub>2</sub> adsorption over the a) CuCo<sub>2</sub>O<sub>4</sub> (220); b) FeCo<sub>2</sub>O<sub>4</sub> (220) and c) NiCo<sub>2</sub>O<sub>4</sub> (220) catalyst surface models.

**Figure S18** The simulated structures of unit cells for (a) NiCo<sub>2</sub>O<sub>4</sub>; (b) FeCo<sub>2</sub>O<sub>4</sub> and (c) CuCo<sub>2</sub>O<sub>4</sub>.

SEM images (Figure S12) show that the precursors of FeCo<sub>2</sub>O<sub>4</sub>, NiCo<sub>2</sub>O<sub>4</sub>, CuMn<sub>2</sub>O<sub>4</sub>, CoMn<sub>2</sub>O<sub>4</sub> and NiMn<sub>2</sub>O<sub>4</sub> with 1D nanofibers structures can be successfully synthesized. More importantly, SEM (Figure S13) and TEM images (Figure S14) confirm that CuMn<sub>2</sub>O<sub>4</sub>, CoMn<sub>2</sub>O<sub>4</sub>, NiMn<sub>2</sub>O<sub>4</sub>, FeCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub> with 1D solid and hollow tubular structures could be also tuned by controlling heating rates. These results imply that the present strategy is effective and versatile for preparing 1D solid and hollow tubular mixed transition metal oxides with different compositions. Among them, hollow tubular NiCo<sub>2</sub>O<sub>4</sub> and FeCo<sub>2</sub>O<sub>4</sub> were further chosen to test NH<sub>3</sub>-SCR performance in comparison with CuCo<sub>2</sub>O<sub>4</sub> and CuCo<sub>2</sub>O<sub>4</sub>-solid. NO<sub>x</sub> conversion at 100-250 °C follows the order: CuCo<sub>2</sub>O<sub>4</sub> > NiCo<sub>2</sub>O<sub>4</sub> > FeCo<sub>2</sub>O<sub>4</sub> > CuCo<sub>2</sub>O<sub>4</sub>-solid (Figure 3a and Figure S15). N<sub>2</sub> selectivity (Figure S16) of NiCo<sub>2</sub>O<sub>4</sub> and FeCo<sub>2</sub>O<sub>4</sub> is more than 95% at 100-400 °C. DFT calculation (Figure S17) was carried out to study the oxygen adsorption energy ( $E_{ads}$ ) on (220) plane over CuCo<sub>2</sub>O<sub>4</sub>, FeCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>.  $E_{ads}$  values confirm that O<sub>2</sub> preferentially adsorbs (Table S3) on the CuCo<sub>2</sub>O<sub>4</sub> (220) surface rather than

NiCo<sub>2</sub>O<sub>4</sub> (220) or FeCo<sub>2</sub>O<sub>4</sub> (220), implying easier formation of oxygen vacancies on CuCo<sub>2</sub>O<sub>4</sub> (220). The simulated structure of unit cell (Figure S18) in CuCo<sub>2</sub>O<sub>4</sub> displays that Cu occupies the octahedral coordination sites.<sup>[19, 20]</sup> and the oxygen-oxygen bond length is changed when Cu is replaced by Ni or Fe. The bond length shortens in NiCo<sub>2</sub>O<sub>4</sub> (1.290 Å) and FeCo<sub>2</sub>O<sub>4</sub> (1.285 Å) with respect to CuCo<sub>2</sub>O<sub>4</sub> (1.437 Å) (Table S3), which is unfavorable for the formation of oxygen vacancies. This observation agrees with the O1s XPS results.

**Table S1** Textural properties and total NH<sub>3</sub> desorption amounts of hollow tubular CuCo<sub>2</sub>O<sub>4</sub> and CuCo<sub>2</sub>O<sub>4</sub>-solid.

Sample	BET surface area (m <sup>2</sup> /g)	Pore volume (cm <sup>3</sup> /g)	The amounts of NH <sub>3</sub> desorption (mmol/g)
CuCo <sub>2</sub> O <sub>4</sub> -solid	45	0.18	1.70
CuCo <sub>2</sub> O <sub>4</sub>	72	0.23	4.34

**Table S2** Surface valence state and O<sub>ads</sub>/(O<sub>latt</sub>+O<sub>ads</sub>) molar ratio.

Sample	Surface valence state	O <sub>ads</sub> /(O <sub>latt</sub> +O <sub>ads</sub> ) (%)
CuCo <sub>2</sub> O <sub>4</sub> -solid	Cu <sup>2+</sup> , Cu <sup>+</sup> , Co <sup>2+</sup> , Co <sup>3+</sup>	54.94
CuCo <sub>2</sub> O <sub>4</sub>	Cu <sup>2+</sup> , Cu <sup>+</sup> , Co <sup>2+</sup> , Co <sup>3+</sup>	63.61
FeCo <sub>2</sub> O <sub>4</sub>	Fe <sup>2+</sup> , Fe <sup>3+</sup> , Co <sup>2+</sup> , Co <sup>3+</sup>	51.94
NiCo <sub>2</sub> O <sub>4</sub>	Ni <sup>2+</sup> , Ni <sup>3+</sup> , Co <sup>2+</sup> , Co <sup>3+</sup>	55.04

**Table S3** The calculated results based on O<sub>2</sub> adsorption over (220) planes in CuCo<sub>2</sub>O<sub>4</sub>, NiCo<sub>2</sub>O<sub>4</sub> and FeCo<sub>2</sub>O<sub>4</sub>.

Sample		E (eV)	d <sub>metal-gas atom</sub> (Å)	D <sub>O-O</sub> (Å)
FeCo <sub>2</sub> O <sub>4</sub> (220)	<i>E</i> <sub>ads-O<sub>2</sub></sub>	-1.60	1.676	1.285
NiCo <sub>2</sub> O <sub>4</sub> (220)	<i>E</i> <sub>ads-O<sub>2</sub></sub>	-1.69	1.688	1.290
CuCo <sub>2</sub> O <sub>4</sub> (220)	<i>E</i> <sub>ads-O<sub>2</sub></sub>	-2.21	2.068	1.437
