To determine the effective electromechanical properties and related parameters of the piezo-active composite with a specific microgeometry (see, for instance, Figs. 2 and 6 in the review paper), it is possible to apply averaging procedures ${ }^{1-4}$ that allow for an electromechanical interaction in the composite sample. In a case of a regular distribution of components in the composite sample, the averaging procedure is based on one of the following methods: the effective field method (the Mori - Tanaka method ${ }^{5}$ generalised for heterogeneous piezoelectric media ${ }^{2,3}$ ), the effective medium method, ${ }^{4,6}$ the matrix method,,$^{1,7}$ or the finite element method (FEM). ${ }^{6,7}$ The effective field method and effective medium method are often regarded ${ }^{2,3}$ as two self-consistent schemes of averaging. These methods are applicable to the $0-3$ and $1-3$ composites ${ }^{1,6,7}$ with piezoelectric inclusions. The shape of the inclusions is either spheroidal ( $0-3$ connectivity) or cylindrical ( $1-3$ connectivity). The matrix method is applied to the composites with planar interfaces. The matrix method is often used to evaluate the effective properties of the composites with elements of $2-$ 2 or 1-3 connectivity. ${ }^{1,7}$ In addition, the dilute approach ${ }^{2,6,7}$ is sometimes applied to predict the effective properties of porous piezo-active media (porous ferroelectric ceramics or composites) with a system of regularly distributed air inclusions in the form of a spheroid. In this case no electromechanical interaction between the isolated air inclusions takes place, and the porous composite is described by 3-0 connectivity.

The effective electromechanical properties of a matrix composite (such as the 1-3 composite in Fig. 6) are represented in the general form ${ }^{4,6,7}$ as

$$
\left\|C^{*}\right\|=\left\|C^{(2)}\right\|+m\left(\left\|C^{(1)}\right\|-\left\|C^{(2)}\right\|\right)\|A\|
$$

where $\left\|C^{(n)}\right\|$ is the $9 \times 9$ matrix of the electromechanical properties of the $\operatorname{RFSC}(n=1)$ and the surrounding polymer medium ( $n$ $=2$ ), $m$ is the volume fraction of the RFSC, and $\|A\|$ is the mechanical strain - electric field concentration matrix that strongly depends on the properties of the components and boundary conditions for mechanical and electric fields in the composite.

The process of FEM is used ${ }^{6,7}$ to carry out an independent evaluation of the effective properties and related parameters of the RFSC-based composites and to compare the FEM data with those related to other methods. Below we show our results on the effective piezoelectric properties and related parameters of the studied RFSC-based composites (Tables S1-S3).

Table S1 comprises data on the 1-3-type composites (Fig. 6) with auxetic polymer matrices. The presence of the polymer component with the negative Poisson's ratio strongly influences the piezoelectric properties of the composite at $m<0.4$, i.e., where the volume fraction of the polymer matrix is relatively large. This influence leads, for instance, to a non-monotonic volumefraction dependence of the piezoelectric coefficient $d_{31}^{*}(m)$ (see the 2 nd column of Table S1) and to a fairly wide volume-fraction range where $d_{31}^{*}(m)>0$. The positive sign of $d_{31}^{*}$ promotes large values of such hydrostatic parameters as $d_{h}^{*}, g_{h}^{*}$ and $\left(Q_{h}^{*}\right)^{2}$. This is the obvious advantage of the 1-3-type RFSC / auxetic polyethylene composites over the 1-3 RFSC / polymer composites wherein the polymer matrix is characterised by a positive Poisson's ratio. It should be noted that the volume fraction $m^{*}$, at which the condition $d_{31}^{*}\left(m^{*}\right)=0$ holds, depends on ratios of elastic constants of the components. For the composites listed in Table S1, one can state that $0.25<m^{*}<0.40$. Data from Table S1 suggest that the largest hydrostatic piezoelectric coefficient $d_{h}^{*}$ is achieved for the composite based on the PMN-0.33PT RFSC. This RFSC exhibits the larger piezoelectric coefficient $d_{h}^{(1)}$ among the components poled along [001] (see Table 1). The inequality $\left[Q_{h}^{*}(m)\right]^{2}>\left[Q_{33}^{*}(m)\right]^{2}$ holds in volume-fraction ranges (see Table S1) wherein the role of the auxetic polymer component is dominating.

In Table S2 we show examples of volume-fraction dependences of some effective parameters of the 1-2-2 composites. The schematic of the 1-2-2 RFSC / polymer-1 / polymer-2 composite is shown in Fig. 10. The results obtained by means of the matrix method and FEM are consistent at various volume fractions $m$ and $m_{s}$. In contrast to the $d_{31}^{*}(m)$ dependences shown in Table S1, now we see the monotonic $d_{31}^{*}(m)$ dependences and $d_{31}^{*}(m)<0$ (see the 3 rd and 7 th columns in Table S2). This behaviour is accounted for by the presence of the polymer components with positive Poisson's ratios. As a consequence, the hydrostatic parameters $d_{h}^{*}, g_{h}^{*}$ and $\left(Q_{h}^{*}\right)^{2}$ decrease in comparison to those from Table S1. It is also seen that the electromechanical coupling factor $k_{33}^{*}$ related to the longitudinal oscillation mode undergoes minor changes when replacing the polymer components at the fixed values of $m$ and $m_{s}$ (see Table S2). This is due to the important role of the anisotropic elastic properties of the laminar matrix of the 1-2-2 composite in forming its electromechanical coupling. It should be added that the $k_{33}^{*}$ values of the composite (Table S2) are about (0.8-0.9) $k_{33}^{(1)}$ of the PMN-0.33PT RFSC.

Table S1. Volume-fraction dependences of piezoelectric coefficients $d_{31}^{*}, d_{33}^{*}$ and $d_{h}^{*}$ (in $\mathrm{pC} / \mathrm{N}$ ), $g_{31}^{*}, g_{33}^{*}$ and $g_{h}^{*}$ (in $\mathrm{mV} \cdot \mathrm{m} / \mathrm{N}$ ), and squared figures of merit $\left(Q_{33}^{*}\right)^{2}$ and $\left(Q_{h}^{*}\right)^{2}$ (in $10^{-12} \mathrm{~Pa}^{-1}$ ) of 1-3-type composites based on [001]-poled RFSCs, FEM calculations

| m | $d_{31}^{*}$ | $d_{33}^{*}$ | $d_{h}^{*}$ | $g_{31}^{*}$ | $g_{33}^{*}$ | $g_{h}^{*}$ | $\left(Q_{33}\right)^{2}$ | $\left(Q_{h}^{*}\right)^{2}$ |

Data from Table S3 allow a comparison of the piezoelectric performance of the 1-2-2 composites wherein the RFSC rods are in the form of either a rectangular parallelepiped or circular cylinder. We observe small differences between the values of $d_{31}^{*}$ evaluated for the related 1-2-2 composites with the regular rod arrangement, however these differences do not lead to considerable changes in the hydrostatic parameters, especially at volume fractions of the RFSC at $m<0.30$.

Finally, the results shown in Tables S1-S3 can promote the manufacturing of novel advanced piezo-active composites with effective parameters from specific ranges of volume fractions.
