## **Variation of phase composition of the $\text{Sr}_2\text{Si}_5\text{N}_8\text{:Eu}^{2+}$ phosphors depending on treatment temperature**

It was noticed that the relative intensity of (400) peak of  $\text{SrSi}_2\text{O}_2\text{N}_2$  was varied with the treatment temperature. The intensity ratio of (400) peak of  $\text{SrSi}_2\text{O}_2\text{N}_2$  and (113) peak of  $\text{Sr}_2\text{Si}_5\text{N}_8$  was used to approximately estimate the  $\text{SrSi}_2\text{O}_2\text{N}_2$  amount in the composition of the resultant powder, as given in Figure 1S. The ratio of  $I(400)/I(113)$  was varied with the treatment temperature: initially, the ratio of  $I(400)/I(113)=0.77$  in the as-synthesized  $\text{Sr}_2\text{Si}_5\text{N}_8\text{:Eu}^{2+}$ ; then it was decreased with increasing temperature and reached to 0.25 after 500 °C-treatment; but, with further elevating temperature, it was increased and ran up to 0.59 via 1200 °C-treatment. This variation trend implies that the  $\text{SrSi}_2\text{O}_2\text{N}_2$  impurity was decomposed through the thermal treatment at relatively low temperature until 500 °C, which might be caused by  $\text{H}_2$  reduction; while, the  $\text{SrSi}_2\text{O}_2\text{N}_2$  was generated again when temperature exceeding 500 °C, which was conceived from that the incomplete reaction from the synthesis process possibly resumed proceeding at relatively high temperature.

## **Synthesis of the $\text{SrSiO}_3$ powder via solid-state reaction**

The raw materials of commercial  $\text{SrCO}_3$  and  $\text{SiO}_2$  powders were used to synthesize the  $\text{SrSiO}_3$  powder for the zeta potential measurement via solid-state reaction at 1350 °C for 3 h. The main phase of the synthesized powder was identified as  $\text{SrSiO}_3$  (JCPDS-ICDD: 34-0099) in XRD patterns of Figure 2S.

### **Effect of the treatment atmosphere on the $\text{Eu}^{2+}$ activator of the $\text{Sr}_2\text{Si}_5\text{N}_8\text{:Eu}^{2+}$ phosphors**

Fourier transform infrared (FT-IR) spectra were recorded by a FT-IR spectroscopy (model 4200, JASCO, Tokyo, Japan), with using standard KBr method. Figure 3S exhibits the FT-IR spectra of the as-prepared, 500 °C-air- and 500 °C- $\text{N}_2\text{-H}_2$ -treated  $\text{Sr}_2\text{Si}_5\text{N}_8\text{:Eu}^{2+}$  powders. The Si-N-Si absorption peaks were assigned to the stretching vibrations at  $\sim 472\text{ cm}^{-1}$ ,  $\sim 926\text{ cm}^{-1}$ , and  $\sim 954\text{ cm}^{-1}$ .<sup>1</sup> The absorption peaks at  $\sim 1630\text{ cm}^{-1}$  and  $\sim 2360\text{ cm}^{-1}$  were corresponding to the molecular vibrations of the  $\text{H}_2\text{O}$  and  $\text{CO}_2$  that were both adsorbed on the sample surface from air.<sup>2, 3</sup> Moreover, a shallow absorption band at  $\sim 1404\text{ cm}^{-1}$  assignable to the Sr/Eu-N bending vibration was found in the as-synthesized  $\text{Sr}_2\text{Si}_5\text{N}_8\text{:Eu}^{2+}$  phosphor.<sup>4</sup> This shallow absorption band was also distinguished in the sample treated in  $\text{N}_2\text{-H}_2$ , but was ambiguous via the thermal treatment in air, implying that the  $\text{Eu}^{2+}$  activator encountered oxidation at 500 °C in air. Therefore the mixture gas of  $\text{N}_2\text{-H}_2$  was more proper than air as an atmosphere for the thermal treatment in this work.

### **Analysis for nitrogen and oxygen contents of the single cross-sectional $\text{Sr}_2\text{Si}_5\text{N}_8$ phosphor particle**

Table 1S exhibits various N/O contents by energy-dispersive X-ray (EDX) analysis at different points, which were numbered in Figure 5a, of the inner part and outmost area in single  $\text{Sr}_2\text{Si}_5\text{N}_8$  phosphor particle thermally-treated at 500 °C in  $\text{N}_2\text{-H}_2$ . The oxygen detection in the inner part of the phosphor particle may come from the epoxy used for cutting the single

particle to prepare the cross section. The content ratios of N/O in the inner part were generally larger than those in the outmost area of the single phosphor particle, in other words, the nitrogen and oxygen contents in the inner part were larger and smaller than those in the outmost area, respectively, further implying surface layer formation around the phosphor particle.

### **Dependence of PL intensity from different emission centers of Eu(SrI) and Eu(SrII) on heating temperature and atmosphere**

Figure 4S shows the PL intensity ratios of Eu(SrI)/Eu(SrII) emission obtained by calculating the integrated intensities of the emission peaks for the as-synthesized and thermally-treated  $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$  phosphors at 300–800 °C in  $\text{N}_2\text{-H}_2$  and (Figure 4Sa) the as-synthesized, 500 °C-air- and 500 °C- $\text{N}_2\text{-H}_2$ -treated  $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$  phosphors (Figure 4Sb). It was noted that the PL intensity ratio of Eu(SrI)/Eu(SrII) emission was increased with arising the temperature of the thermal treatment, probably indicating that the crystal field splitting and electron-lattice coupling of the phosphor were dependent on the treatment temperature irrespective of the treatment in  $\text{N}_2\text{-H}_2$  or air and therefore high heating temperature made Eu(SrI) emission center to be active.

### **Thermal degradations on PL intensities of the $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$ phosphors thermally treated in $\text{N}_2\text{-H}_2$ at 300 °C and 800 °C**

Figure 5S exhibits the temperature-dependent relative PL intensities of the (a) 300 °C- and (b) 800 °C-treated  $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$  phosphors in  $\text{N}_2\text{-H}_2$  with heating up to 300 °C and cooling down to 30 °C. After the cooling down, the relative PL intensity was 96.9% of the initial PL intensity at 300 °C treatment and was 99.8% of the initial PL intensity at 800 °C treatment, which was the same as that (99.8%) at 500 °C. By considering the negative effect upon the PL intensity lost caused by treatment temperature (Figure 6a), 500 °C seems a most suitable treatment temperature in this work.

#### **Variation in absolute PL intensities of the as-received and 500 °C- $\text{N}_2\text{-H}_2$ -treated $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$ phosphors with heating and cooling temperature**

Figure 6S demonstrates the variation in absolute PL intensities of the as-received and 500 °C- $\text{N}_2\text{-H}_2$ -treated  $\text{Sr}_2\text{Si}_5\text{N}_8:\text{Eu}^{2+}$  phosphors with temperature heating up and cooling down. Even though herein the PL absolute values were used to plot the YOYO tendency varied with heating and cooling temperature, it was still found that when temperature cooling down to room temperature, the recover PL intensity in absolute value for the thermally-treated phosphor was obviously higher than for the as-received one, indicating the effect of the passivation surface layer formed by heating treatment on reducing thermal luminescence degradation.
