

Revisiting an old concept: the coupled oscillator model for VCD.

Part 1: The generalised coupled oscillators mechanism and its intrinsic connection to the strength of VCD signals

1 GCO analysis: (R)-2,2'-spirobi[indene]-1,1'(3H,3'H)-dione

This section describes the GCO analysis performed for all normal modes of the molecular complex formed between one (R)-2,2'-spirobi[indene]-1,1'(3H,3'H)-dione molecule and two chloroform solvent molecules.

When analysing different types of normal modes, different definitions of the GCO fragments **A**, **B** and **R** need to be used, viz. different types of normal modes involve movements of different groups of atoms. From the perspective of the GCO analysis one can distinguish between four main types of normal modes: I) modes localised entirely on the solute molecule, II) modes localised entirely on the solvent molecules, III) modes that are localised on the solute and solvent molecules, and IV) modes that involve strong movements of the central C atom. Fig. 1 shows the definitions of the molecular fragments **A**, **B** and **R** used in the GCO analysis of these four types of modes. The results of the GCO analysis are listed in Tables I and II.

[Figure 1 about here.]

It should also be noted that Eq. 19 in the manuscript is properly defined only when R_{01}^{CO} is not zero. If R_{01}^{CO} is zero or very small, there is no reason to consider R_{01}^{COC} as a correction for R_{01}^{CO} . Since many modes have small R_{01}^{CO} terms and thus very large $a(j)$ factors, this information is not shown in Tables I and II.

[Table 1 about here.]

[Table 2 about here.]

2 GCO analysis: dehydroquinidine

For simplicity, a GCO analysis was performed for DHQD by dividing the molecules in only two fragments. In this case, the expression describing the fragment decomposition of the rotational strength becomes:

$$R_{01}(j) = -i \cdot \vec{E}_{01}(j) \cdot \vec{M}_{10}(j) = R_{01}^{\text{IF}}(j) + R_{01}^{\text{GCO}}(j) \quad (1)$$

where:

$$R_{01}^{\text{IF}}(j) = -i \cdot [\vec{E}_{01}^{\text{A}}(j) \cdot \vec{M}_{10}^{\text{A}}(j) + \vec{E}_{01}^{\text{B}}(j) \cdot \vec{M}_{10}^{\text{B}}(j)] \quad (2)$$

$$R_{01}^{\text{GCO}}(j) = -i \cdot [\vec{E}_{01}^{\text{A}}(j) \cdot \vec{M}_{10}^{\text{B}}(j) + \vec{E}_{01}^{\text{B}}(j) \cdot \vec{M}_{10}^{\text{A}}(j)] \quad (3)$$

As before, $R_{01}^{\text{IF}}(j)$ represents the contribution to the total rotational strengths from the individual fragments, whereas R_{01}^{GCO} describes the contribution resulting from the interaction of the two fragments.

The normal mode motion was also analysed by computing the percent localisation of the mode motion on the two CO fragments:

$$\Lambda^{\mathbf{X}}(j) = \frac{\sum_{\sigma=1}^{N^{\mathbf{X}}} |\vec{Q}^{\sigma}(j)|}{\sum_{\lambda=1}^N |\vec{Q}^{\lambda}(j)|} \quad (4)$$

where $|\vec{Q}^{\lambda}(j)|$ is the length of the nuclear displacement vector $\vec{Q}^{\lambda}(j)$ (i.e. the eigenvectors of the mass-weighted Hessian) associated with atoms λ and the normal mode j , N the total number of atoms, $N^{\mathbf{X}}$ the total number of atoms in fragment \mathbf{X} .

Tables III–VI list the results of the GCO analysis performed using the CO fragments defined in Fig. 2.
