**Figure S1.** Free energy profiles (FEPs) of (A) eco, (B) hiv, (C) lc11 and (D) bh RNase-H show the scaled free energies ( $\Delta G/k_B T$ ) as a function of the fraction of native contacts formed ( $Q$ ) (see Methods). FEPs calculated from SBMe are in grey and from SBMw are in black. Error bars on the FEPs are shown in a different color for ease of visualization. U and F correspond to the unfolded and folded ensembles. I, F' and X are partially folded ensembles that are discussed in main text.

**Figure S2.** Flat-weighting CORE contacts modulates the CORE-periphery packing energy distribution and can cause a change in the folding routes of ecoRNase-H. 2DFES's of ecoRNase-H calculated from (A) SBMe and (B) SBMw are reproduced from Fig. 2A and 3A for ease of comparison. When the contacts shown in red on (C) the ecoRNase-H structure are flatweighted, the folding route is altered from (B) to that shown in the 2DFES of (D). (The origin of these contacts is discussed in S. Yadahalli and S. Gosavi, J. Mol. Biol. 428, 509-521, 2016.) In contrast, the 2DFES's of bhRNase-H calculated from (E) SBMe and (F) SBMw are very similar. These are reproduced from Fig. 2D and 3D for ease of comparison.

**Figure S3.** An example difference contact map used for calculating the number of lost and gained contacts in the RP method. A coloured square on the contact map at (x, y) implies that a contact is present between residues x and y in the ecoRNase-H structure. Contacts not present in the average RP but present in WT ecoRNase-H are shown in red and contacts not present in the WT ecoRNase-H but present in the RP are shown in blue. Contacts present in both the average RP and the WT are shown in grey. The red and blue contacts are further partitioned into CORE and periphery contacts for plotting Fig. 5. The average RP is created as follows: The frequency of every contact in the 200 RPs is calculated. The most frequently occurring N contacts are chosen to be in the average RP, where N is the number of contacts in WT ecoRNase-H. This average RP is not directly used in the analysis. However, it can be used for understanding which regions of the protein lose (or gain) the most contacts upon random permutation. In ecoRNase-H, CORE (the central red dashed square; residues 43 to 122) loses the most contacts.

**Figure S4.** A pairwise structure-based sequence alignment for all pairs of sequences is calculated using the STAMP algorithm of VMD <sup>62,63</sup>. CORE regions of the proteins are enclosed in red boxes. The six aromatic residues of ecoRNase-H CORE whose contacts are responsible for the change in the folding route (Fig. S2) are marked by blue rectangles on the eco RNase-H alignment profiles. The

residues that they align with are also shown. No more than two of the aligned residues are aromatic residues in the other proteins.
