Calculation methods:

$$\square x_a = \frac{P_{atm} V_{H2} / RT}{n_{FA}} \quad (S1)$$

Where  $x_a$  is conversion,  $P_{atm}$  is the atmospheric pressure (101325 Pa),  $V_{H2}$  is the generated volume of  $H_2$ ,  $R$  is the universal gas constant ( $8.3145 \text{ m}^3 \cdot \text{Pa} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ ),  $T$  is room temperature (278 K), and  $n_{FA}$  is the mole number of FA.

□

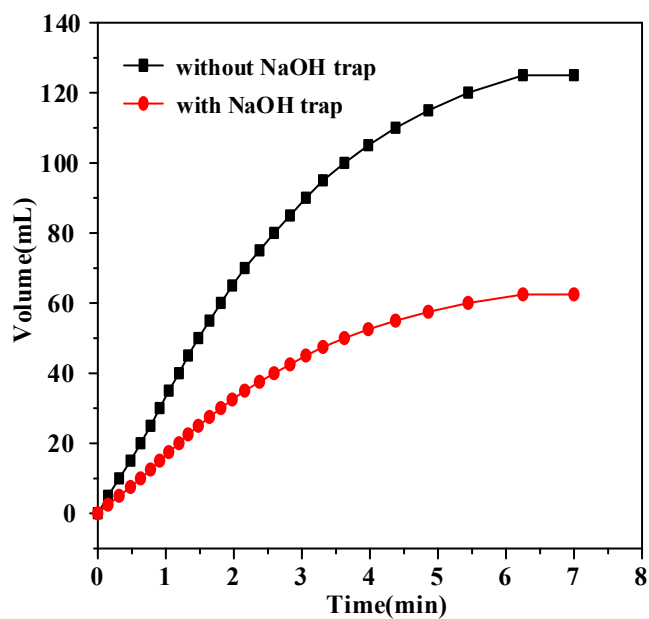

$$\square TOF_{initial} = \frac{P_{atm} V_{H2} / RT}{n_{Ag+Pd} t} \quad (S2)$$

Where  $TOF_{initial}$  is initial turnover frequency when  $x_a$  reaches 20%,  $n_{Ag+Pd}$  is the mole number of the Ag and Pd, and  $t$  is the reaction time when  $x_a$  reaches 20%.
