## Supplementary computational analyses

### Investigations of water wire effect on ATPase reaction

Extensive studies have found that it would be more effective to utilize more than one water molecule to relay and complete proton transfer in hydrolysis reaction.<sup>1-6</sup> Because in AceK the room between  $\gamma$ -phosphoryl and the proton acceptor Asp457 is able to accommodate two lytic water molecules, we also studied the two-water hydrolysis mechanism of AceK. Similar to that in the single-water mechanism, we found that the dissociative pathway is the favorable one in the two-water mechanism. The calculated energy barriers for associative and dissociative mechanisms are 31.21 kcal·mol<sup>-1</sup> and 21.33 kcal·mol<sup>-1</sup>, respectively. The geometries of reactants, transition states and products are depicted in Figure S2 and key structural parameters are listed in Table S2.

In the two-lytic-water pathway, the second water molecule acts as a bridge between the lytic water and Asp457. When the OH<sub>wat1</sub> of the lytic water attacks the  $\gamma$ -phosphates of ATP, a proton is transferred to the bridge water, which gives out another proton to Asp457 at the same time (Scheme S1). Comparing to that of Model<sub>1-wat</sub>, the calculated 21.33 kcal·mol<sup>-1</sup> energy barrier indicates that the two-lytic-water pathway for ATPase reaction is energetically unfavorable. For the dissociative structures of the two-lytic-water pathway, the strong hydrogen bonding interaction between the lytic water and O <sub>$\gamma$ 2</sub> of ATP (O<sub>wat1</sub>-O <sub>$\gamma$ 2</sub>ATP=2.82 Å) in reactant hinders the movement and nucleophilic attacking of the lytic water, which may contribute to a

higher energy barrier. Furthermore, although there is room to accommodate two water between ATP and Asp457, one more water causes extra steric conflicts in the active site, which would also be a reason of slowing ATP hydrolysis. In conclusion, the dissociative mechanism with one lytic water is the most reasonable and energetically favorable pathway for ATPase reaction.

### **Investigations of the number of Mg<sup>2+</sup> in active center on ATPase activity of AceK**

It is well known that one important role played by AceK in the cell is its kinase function. Typical kinases such as ePKs usually contain two Mg<sup>2+</sup> ions (or other metal ions) in their active sites. AceK, however, contains only one Mg<sup>2+</sup> ion in its active site.

Similar to our previous work on kinase and phosphatase of AceK<sup>7, 8</sup>, we further investigated ATP hydrolysis using a double-Mg<sup>2+</sup> model of AceK. In this case, the second Mg<sup>2+</sup> ion was manually added in the active site with the similar position observed in ePKs. The added Mg<sup>2+</sup> ion is coordinated with  $\gamma$ -phosphates of ATP and the carboxylate group of Asp457 to balance the local negative charges. In addition, three water molecules are included to complete the coordination of the second Mg<sup>2+</sup> ion. The final model has a net charge of +1. Similarly, the ATP hydrolysis reaction was analyzed for both associative and dissociative pathways. The geometries of reactants, transition states and products are depicted in Figure S3 and key structural parameters are listed in Table S3.

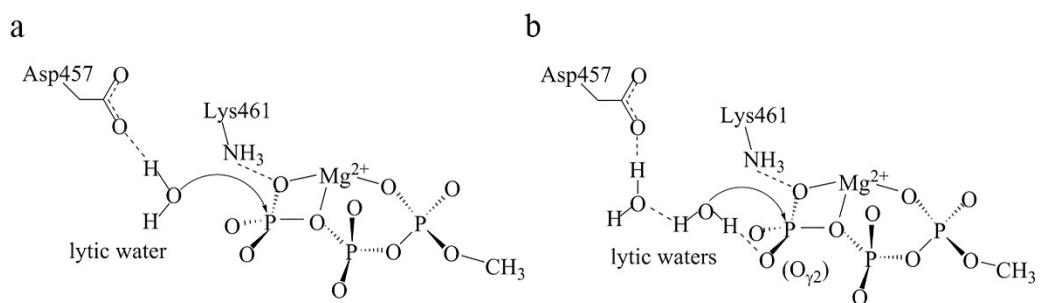

Our results show that the added Mg<sup>2+</sup> severely hinders ATP hydrolysis with higher energy barriers of 45.91 kcal·mol<sup>-1</sup> for associative mechanism and 29.16 kcal·mol<sup>-1</sup>

for the dissociative one. Note that the unique single Mg<sup>2+</sup> ion in ATPase stabilizes the reactant, transition state and product by its octahedral coordination with α-, β- and γ-phosphoryl groups of ATP, Asn462, Asp475 and one water molecule, same as reported in our kinase study. In the double-Mg<sup>2+</sup> model, the active site is unable to fully accommodate the octahedral coordination for the second Mg<sup>2+</sup> ion throughout the reaction. Furthermore, the added Mg<sup>2+</sup> also makes the space more crowded for the ATP hydrolysis and makes this reaction more difficult to happen.

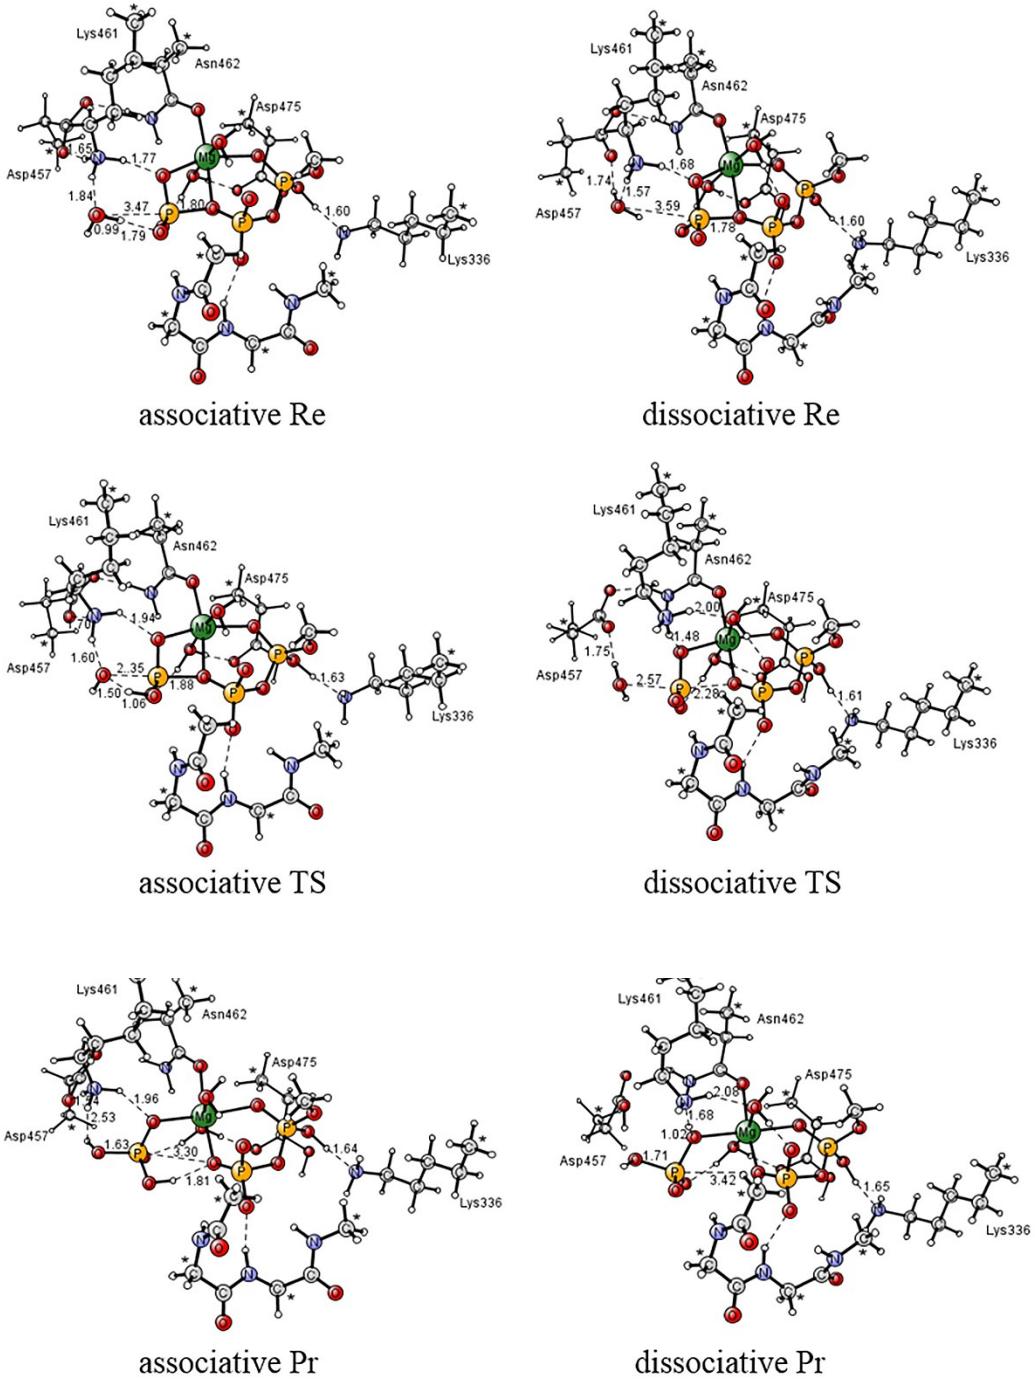

### **Further discussion of ATPase and kinase activities of AceK**

AceK integrates kinase, phosphatase and ATPase activities at the same active site. Because AceK possesses much higher ATPase activity than the other two activities, it seems reasonable that ATP hydrolysis is the main source for ADP which is essential for its phosphatase activity. In order to gain deeper understanding, the Mulliken charges of critical atoms were analyzed for both ATPase model and kinase model (Table S5). Clearly, P<sub>γ</sub> of reactant is more positive in ATPase model than that in kinase model, while O<sub>wat</sub> of reactant in ATPase model is more negative than O<sub>ser113</sub> in the kinase model. The stronger electrophilicity of the γ-phosphates in ATP and nucleophilicity of the lytic water may enable AceK to have much higher ATPase activity than its kinase activity.
