

### *Mechanical properties*

The TS (MPa) was calculated by following equation:

$$TS \text{ (MPa)} = \frac{P_{\max}}{A} \quad \text{Eq. (1)}$$

where  $P_{\max}$  is the maximum force (N) necessary to pull the sample apart, and A is the initial cross-sectional area of the sample film ( $\text{m}^2$ ) determined by multiplying the film width by the film thickness.

The percentage elongation at break point is the amount of uni-axial strain at fracture, was calculated by following equation:

$$EAB(\%) = \frac{(l_b - l_0)}{l_0} \times 100 \quad \text{Eq. (2)}$$

where  $l_b$  is the film elongation at the moment of failure and  $l_0$  is the initial grip length (3 cm) of samples multiplied by 100.

Modulus of elasticity (E) was expressed in MPa and was calculated from the slope of the linear region of an engineering stress-strain curve:

$$E \text{ (MPa)} = \frac{\Delta S}{\Delta e} \quad \text{Eq. (3)}$$

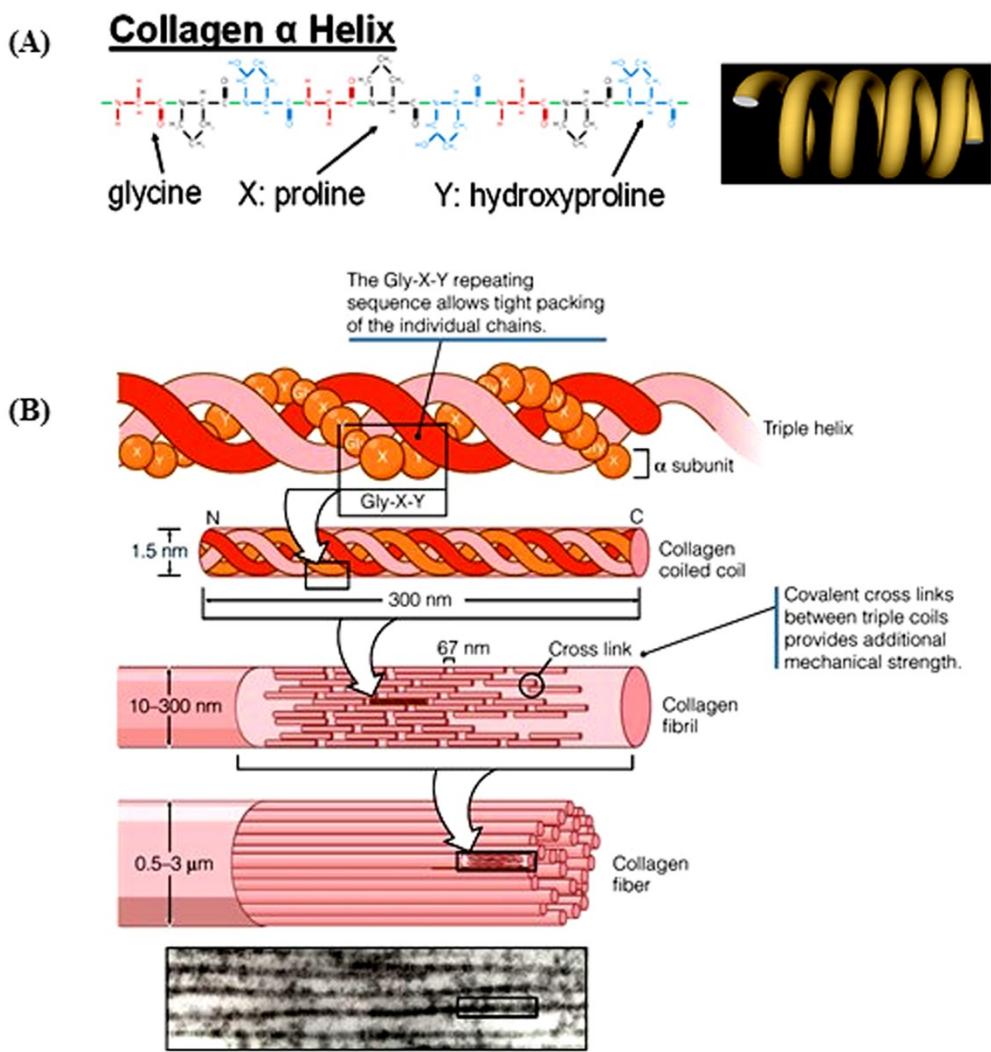

where  $\Delta S$  is the change in tensile stress and  $\Delta e$  is the change in tensile strain over the elastic region.

### *Water vapour permeability*

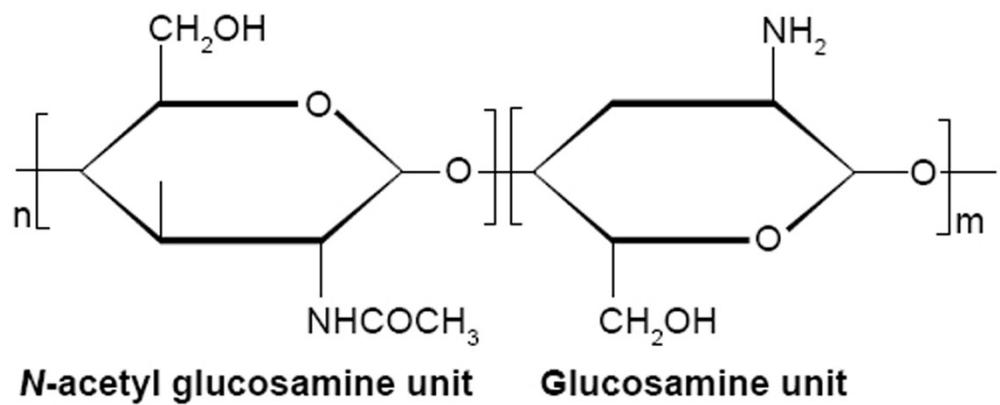

Briefly, films were sealed on an aluminium permeation cup containing dried silica gel (0 % RH) with silicone vacuum grease and rubber gasket, and held with four screws around the cup's circumference. After taking the initial weight of the test cups, they were placed in a desiccator containing the distilled water (30 °C, 50±2 % RH), followed by weighing the test cup to the nearest 0.0001 g with an electronic scale (Sartorius Corp.) after every 1 h intervals over an 8 h period.

### *Film solubility*

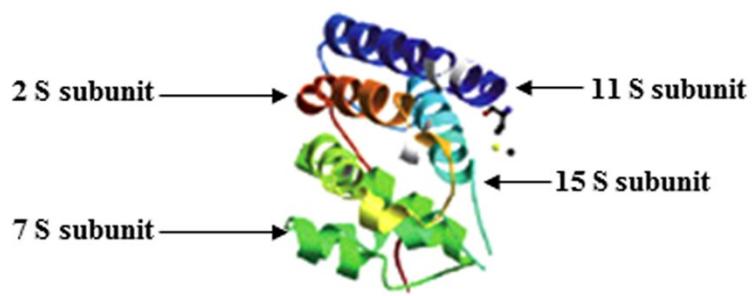

Two pieces of conditioned films ( $3 \times 2 \text{ cm}^2$ ) previously dried until constant weight, were weighed and immersed in 10 mL of distilled water containing 0.1 % (w/v) sodium azide in 50 mL screw cap tubes. The tubes were capped, placed in a shaking water bath (Heidolph UNIMAX 1010, Schwabach, Germany) and mixtures were shaken continuously at room temperature for 24 h. Undissolved debris was obtained after centrifugation at  $3000 \times g$  for 10 min at 25 °C using a centrifuge (Allegra 25R Centrifuge, Beckman Coulter, Krefeld, Germany). The pellets were dried at 105 °C for 24 h to obtain the dry unsolubilised film matter.
