Calculation of Electrochemical Details for Typical Synthesis Procedure. The conditional reduction potential $E_{\mathrm{AA}}$ for AA in equation 3 can be described as follows (modified from reference 35):

$$
\begin{equation*}
E_{\mathrm{AA}}^{\prime}=0.553-\frac{R T}{F} \mathrm{pH}+\frac{R T}{F} \ln \frac{\left[A A_{\mathrm{O}}^{-}\right]}{\left[A A_{\mathrm{R}}^{-}\right]}+\frac{R T}{2 F} \ln \frac{K_{\mathrm{O}}}{K_{\mathrm{R}}}-\frac{R T}{2 F} \ln \frac{K_{\mathrm{O}}+\left[H^{+}\right]}{K_{\mathrm{R}}+\left[H^{+}\right]} \tag{S1}
\end{equation*}
$$

where $\left[A A_{\mathrm{O}}{ }^{-}\right]$and $\left[A A_{\mathrm{R}}{ }^{-}\right]$indicate the equilibrium concentrations of AA in oxidative and reductive states, respectively. $K_{\mathrm{O}}$ and $K_{\mathrm{R}}$ are the first dissociation constants of the oxidized and reduced AA, respectively. Because of its weak acidity, AA with the oxidative form can be considered as a monovalent acid, and the values of $p K_{\mathrm{O}}$ and $p K_{\mathrm{R}}$ are given as 9.0 and 4.17. Considering the dosage of AA and ignoring the influence of other ions, the initial pH of the reaction system is 2.82 .

Under typical synthesis procedure, when the reduction process is complete, the equilibrium concentrations of $\left[\mathrm{PdCl}_{4}\right]^{2-}, \mathrm{Cl}^{-},\left[\mathrm{AA}_{\mathrm{O}}\right]^{-}$, and $\left[\mathrm{AA}_{\mathrm{R}}\right]^{-}$are calculated to be $1.008 \mathrm{8} 10^{-6}, 8.008 \mathrm{8} 10^{-2}$, $2.00810^{-2}$, and $1.41810^{-2} \mathrm{~mol} / \mathrm{L}$, respectively. Hence, the value of $E_{\mathrm{AA}}^{\prime}$ is 0.306 V , and the conditional reduction potential for $\left[\mathrm{PdCl}_{4}\right]^{2-/} \mathrm{Pd}$ is 0.534 V .

Calculation of the Mole Fraction of Br in a Pd Nanocube. Because of the close values of the size of $\mathrm{Br}^{-}\left(r_{\mathrm{Br}}\right)$ and the distance of $\mathrm{Pd}(200)$ faces $(0.5 a)$, we define $2 r_{\mathrm{Br}}$ to be equal to $a$ for simplification. Hence, the value for lattice constant of Pd is $a$. For a Pd nanocube with edge length of $n$, the number of atoms on surfaces is $N$, and the total amount of Pd atoms in the cube is $N_{\mathrm{Pd}}$

$$
\begin{equation*}
N=2 \times 6 \times \underset{a}{\stackrel{n}{-})^{2}}=\frac{12 n^{2}}{a^{2}} \tag{S2}
\end{equation*}
$$

$$
\begin{equation*}
N_{\mathrm{Pd}}=4 \times \underset{\underset{a}{(-)}}{ }{ }^{3}=\frac{4 n^{3}}{a^{3}} \tag{S3}
\end{equation*}
$$

According to Scheme 2, every two Pd atoms possess one $\mathrm{Br}^{-}$, and the number of $\mathrm{Br}^{-}$on cubic surface is $N_{\mathrm{Br}}$.

$$
\begin{equation*}
N_{\mathrm{Br}}=\frac{1}{2} N=\frac{6 n^{2}}{a^{2}} \tag{S4}
\end{equation*}
$$

Consequently, the mole fraction $\mathrm{Br}^{-}$in Pd cube is $\chi$.

$$
\begin{equation*}
\chi=\frac{N_{\mathrm{Br}}}{N_{\mathrm{Pd}}}=\frac{3 a}{2 n} \tag{S4}
\end{equation*}
$$

DFT Calculations. To analysis the properties of different Pd low-index facets, First-principle DFT calculations were employed with the pseudo-potential plane-wave method. Three different facets with 5 layer atomic thickness, namely $\{100\},\{110\}$ and $\{111\}$, were cleaved and covered by a vacuum slab of $10 \AA$. The geometries are full optimized via generalized gradient approximation (GGA) with Perdew-Burke-Ernzerhof (PBE) approximation ${ }^{1}$. The $k$-point was defined at $2 \times 2 \times 1$. The calculations of electron density maps (Scheme S1) were performed with CASTEP ${ }^{2}$.

To study the physical adsorption behavior of $\mathrm{Br}^{-}$onto the top layer of $\mathrm{Pd}\{100\}$ facet, classical grand canonical Monte Carlo (GCMC) simulations were applied through Adsorption Locator module ${ }^{3,4}$. The simulations were performed with the standard universal force field (UFF) in the temperature range of $300-500 \mathrm{~K}$. The $\mathrm{Br}^{-}$was adsorbed onto the octahedral cavity (Scheme S2) with adsorption energy of $-0.8863 \mathrm{kcal} / \mathrm{mol}$.

Fig. S1. HRTEM images of twinned crystals generated while preparing Pd nanocubes: (A) decahedron, (B) icosahedron, (C) triangular bipyramid and (D) pentagonal rod. Images inserted indicate the corresponding FFT pattern of each structure.

Fig. S2. TEM images of Pd nanocrystals reacted for (A) 3, (B) 7 and (C) 10 h under typical synthesis procedure. Scale bar: 50 nm .

Fig. S3. TEM images of Pd nanocrystals prepared under typical synthesis procedure where KBr was replaced by same concentrations of $(\mathbf{A}) \mathrm{KI}$ or $(\mathbf{B}) \mathrm{KCl}$, or same amount of $(\mathbf{C}) \mathrm{K}_{2} \mathrm{PdBr}_{4}$ was occupied instead of $\mathrm{K}_{2} \mathrm{PdCl}_{4}$. Scale bar: 50 nm .

Fig. S4. TEM images of Pd nanostructures obtained with different concentrations of $\mathrm{KBr}(\mathrm{mmol} / \mathrm{L})$ :
(A) 630 ,
(B) 315, (C) 158,
(D) 78.8 to
(E) 0 . Scale bar: 20 nm . (Width: the mean width of nanostructures; Avg. $L / W$ : the average aspect ratio.)

Fig. S5. TEM image and size distribution of Pd nanocubes gained with the concentration of KBr at $1.26 \mathrm{~mol} / \mathrm{L}$.

Fig. S6. TEM images of as-synthesized Pd nanoparticles based on the concentrations of reagents in

Table S 1 with AA as reducing agent and KBr as capping agent. Scale bar: 50 nm .

Table S1. Reagent concentrations for each reaction.

| Items |  | Dosage of $\mathrm{KBr} / \mathrm{mmol} / \mathrm{L}$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | 67.2 | 134 | 269 | 538 | $1.08 \times 10^{3}$ |
| 300B$\vdots$4000000 | 22.7 | 1 | 2 | 3 | 4 | 5 | 6 |
|  | 45.4 | 7 | 8 | 9 | 10 | 11 | 12 |
|  | 90.8 | 13 | 14 | 15 | 16 | 17 | 18 |
