1 **1. The XPS analysis of Fe_3O_4 and $\text{Fe}_3\text{O}_4@\text{mTiO}_2$.**

2 XPS analysis was carried out to elucidate the detailed surface chemical
3 composition of synthesized nanoparticles' surface. As shown in Figure S2A, the main
4 peaks of Fe_3O_4 are C 1s, O 1s and Fe 2p centered at 284.9 eV, 530.1 eV and 710.6 eV,
5 respectively. In the $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ nanocomposites spectrum (Figure S2B), a new
6 peak appears at 459.7 eV, assigned to the photoelectrons originating from the Ti 2p
7 energy level, which responds to the Ti element in the nanocomposites photocatalyst.
8 Compared with Fe_3O_4 spectrum, the signal of Fe 2p decreases and nearly disappears,
9 which is in response to the TiO_2 content in $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ nanocomposites.
10 Furthermore, the Ti 2p high resolution XPS spectra are showed in Figure S2-B
11 (insert). The two peaks centered at 464.2 and 458.5 eV are well corresponded to Ti
12 $2p_{1/2}$ and Ti $2p_{3/2}$ binding energies. And the splitting energies between them are 5.7
13 eV, indicating a normal state of Ti^{4+} in the $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ nanocomposites. These
14 results suggested that Fe_3O_4 and TiO_2 were present mainly as separated phases in the
15 $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ nanocomposites.

16 **2. The magnetic properties analysis of Fe_3O_4 , $\text{Fe}_3\text{O}_4@\text{TiO}_2$, and $\text{Fe}_3\text{O}_4@\text{mTiO}_2$.**

17 The magnetic properties of the prepared samples were measured with a VSM.
18 Figure S3 shows the magnetization (M–H) curves of Fe_3O_4 , $\text{Fe}_3\text{O}_4@\text{TiO}_2$, and
19 $\text{Fe}_3\text{O}_4@\text{mTiO}_2$. It can be seen that saturation magnetization value of $\text{Fe}_3\text{O}_4@\text{TiO}_2$ (34
20 emu/g) is much lower than that of the bare Fe_3O_4 (68 emu/g). The decrease in
21 saturation magnetization is mainly due to the non-magnetic titanium dioxide content
22 in the nanocomposites. After mesoporous treatment, the saturation magnetization

1 value of $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ (37 emu/g) is little higher than $\text{Fe}_3\text{O}_4@\text{TiO}_2$ (34 emu/g)
2 because of the mesoporous structure on the surface. Besides, the coercivity (H_c) and
3 remanent magnetization (M_r) of the $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ nanocomposites are close to zero,
4 indicating that $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ photocatalyst exhibits superparamagnetic properties at
5 room temperature. With superparamagnetic properties, the magnetic photocatalyst can
6 be recovered efficiently by imparting an external magnetic field and no residual
7 magnetism exists after removal of the applied magnetic field. Therefore, the prepared
8 $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ photocatalyst can be easily redispersed in solution for recycling.

9 **3. Photocatalytic activity of Moncrotophos in aqueous solution under visible light.**

10 In addition, we also evaluated the photocatalytic activity under visible light
11 because of the $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ photocatalyst improves the titania response from the
12 UV to the visible region. The experimental conditions are same as the test of
13 photocatalytic activity of Moncrotophos in aqueous solution with $\text{Fe}_3\text{O}_4@\text{mTiO}_2$
14 except for visible light. The photocatalytic degradation of Moncrotophos in the
15 presence or in the absence of the $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ photocatalyst is presented in Figure
16 S4. The result shows that illumination in the absence of $\text{Fe}_3\text{O}_4@\text{mTiO}_2$ does not result
17 in the distinct photocatalytic degradation of Moncrotophos. And in the presence of
18 $\text{Fe}_3\text{O}_4@\text{mTiO}_2$, the concentration of Moncrotophos decreases substantially with
19 continued illumination of visible light. While, the photocatalytic efficiency under
20 visible light is much lower than that of UV light. According to Figure S4, we can
21 calculate that about 30% of Moncrotophos can be photo-degraded with 60 min
22 visible light illumination, yet, total of that with UV light. From the result we can

1 deduce that the Fe₃O₄@mTiO₂ photocatalyst actually improves the titania response
2 from the UV to the visible region.

3 **4. Zeta potential analysis of Fe₃O₄@mTiO₂.**

4 Zeta potential was also analyzed at different pH values in order to study the
5 surface properties of Fe₃O₄@mTiO₂. The zeta potential of nanocomposites in
6 suspensions is probably controlled by the pH through the following process:

8 As shown in Figure S7, the zeta potential vs. pH curve for Fe₃O₄@mTiO₂ was similar
9 with that for pure TiO₂ (P-25), suggesting the small influence of the existence of
10 Fe₃O₄ on zeta potential of TiO₂ mesoporous shell. The isoelectric point (IEP) of
11 Fe₃O₄@mTiO₂ and P-25 in deionized water was 6.0 and 7.0, respectively, which is
12 close to the values reported in the literature. The lower IEP of Fe₃O₄@mTiO₂
13 nanocomposites suggests better dispersions stability around neutral pH, as compared
14 P-25, due to a larger repulsive electrostatic interaction. The difference of zeta potential
15 might be due to the changes in specific surface area and the adsorptive abilities to
16 hydroxyl ions on surface of Fe₃O₄@mTiO₂. Besides, the mesoporous treatment
17 process of the Fe₃O₄@mTiO₂ could alter the surface energy, which results in different
18 adsorption and affinity of protons on the surface. These factors contribute to the minor
19 changes of the zeta potential of Fe₃O₄@mTiO₂.
