## 2. Selection of microsolvated system and other computational details

In our 10 ps NVT MD simulations of aqueous 2,4-dithiothymine, we found a compact 4-water hydrogen-bond networks always around the two C=S bond. Thus, we adopted this minimally microsolvated model.

This situation is different from 7-water hydrogen-bonded network used in 4-thiothymine system recently by Martínez-Fernández et al. (ref. 47). This can be understandable. In terms of our previous QM/MM work on 4-thiothymidine, ref. 46, it is easily found that the hydrogen-bonding interaction is much stronger between the C=O group and water molecules than that between the C=S group and water molecules. Thus, more waters cluster around the C=O group and less waters around the C=S group. This has been observed in recent QM/MM work of Martínez-Fernández and coworkers (see Fig. S3 in their work). In 2,4-dithiothymine system, there is no C=O group, only the C=S groups; thus, the total number of water molecules that are compactly hydrogen-bonded with the two C=S groups is reduced, as observed in our 10 ps MD simulations.

All two-state minimum-energy conical intersections in Figs. 9-11 are directly optimized at CASSCF level using the penalty-function based method. Their single-point energies are refined by MS-CASPT2 method. Of course, at CASSCF level, they are truly degenerate points; but, at MS-CASPT2 level, a reasonably small energy gap, ca. 2-3 kcal/mol, turns out, as shown in Table 3. In addition, we have also identified some three- and four-state degenerate points based on MS-CASPT2 computed LIIC paths (Figs. S1-S6). The latter ones are not directly optimized.
