Supporting Information

Antonin Leblanc, Nicolas Mercier,* Magali Allain, Marie-Claire Dul, Guy Weber, Nicolas Geoffroy, Jean-Pierre Bellat and Igor Bezverkhyy*

A robust Viologen and Mn-based porous coordination polymer with two types of Lewis acid sites providing high affinity for H₂O, CO₂ and NH₃.

I- Synthesis of (H4pc3)(Cl)2

The synthesis of the $(H_4pc3)(Cl)_2$ has been obtained in two steps according to the Zincke reaction (Figure S1). The first step is the synthesis of the Zincke salt of 4,4'-bipyridinium, 1,1'bis-(2,4-dinitrophenyl) dichloride. In a 50 mL flask, 1.562g (10 mmol, 1 eq) of 4,4'-bipyridine is added to 4.051g (20 mmol, 2 eq) of 1-chloro-2,4-dinitrobenzene, and 25 mL of ethanol (96%). The mixture was heated under reflux and stirred for 48 hours, then the precipitate was filtered off and washed with ethanol (96%), acetone and dried with diethyl ether. The second step is the synthesis of the expected salt. In a 50 mL flask, 5.613g (10 mmol, 1eq) of 4,4'-bipyridinium-1,1'bis-(2,4-dinitrophenyl) dichloride are added to 3.623g (20 mmol, 2 eq) of 5-aminoisophtalic acid, and 25 mL of ethanol (96%). The mixture was heated under reflux and stirred for 48 hours. The solid was filtered off and washed with ethanol (96%), acetone and dried with diethyl ether. The second step is the synthesis of the expected salt. In a 50 mL flask, 5.613g (10 mmol, 1eq) of 4,4'-bipyridinium-1,1'bis-(2,4-dinitrophenyl) dichloride are added to 3.623g (20 mmol, 2 eq) of 5-aminoisophtalic acid, and 25 mL of ethanol (96%). The mixture was heated under reflux and stirred for 48 hours. The solid was filtered off and washed with ethanol (96%), acetone and dried with diethyl ether. The compound was characterized by ¹H NMR (300 MHz – olid solubilized in DMSO-d₆) (Figure S2). The general yield of the synthesis is

Figure S1 : Synthesis $(H_4pc3)(Cl)_2$ leading to a general yield of 32%.

Figure S2 : 1H NMR of (H₄*pc3*)(Cl)₂ solubilzed in deuterated DMSO.

II- Synthesis of [Mn(pc3)(H₂O)₂].xH₂O

The PCP [Mn(*pc3*)(H₂O)₂]x.H₂O (x \approx 3.5) was obtained as pure phase by hydrothermal method : 3mg of (H₄*pc3*)(Cl)₂ are added to 8mL of a saturated water solution of (H₄*pc3*)(Cl)₂ whose pH was fixed to pH=7 thanks to the addition of a suitable quantity of triethylamine ; then 100mg of MnCl₂.4H₂O were added to this solution ; the heating program was set to : 50 hours from RT to 160°C, 160 °C for 20 hours, and a final cooling step from 160 °C to RT for 12 hours. The sample was filtered off and dried in air. In Fig. S3, the XRPD pattern of the sample is compared to the theoretical one calculated from the crystal structure of **1**. All positions of experimental lines well fit with the expected ones showing that the phases has been obtained as a pure phase. Moreover, the C, N, H elemental analyses which have been carried out, the values well corresponding to the expected ones for a formulation of [Mn(*pc3*)(H₂O)₂]3.5 H₂O (exp: C: 48.65, N: 4.29, H: 3.80; calc: C: 49.02, N: 4.40, H: 3.92).

Figure S3 : Experimental and theoretical XRPD of $[Mn(pc3)(H_2O)_2]x.H_2O$.

III- Crystal structure of [Mn(pc3)(H₂O)₂].3H₂O

While the TGA analysis and elemental analysis give a formulation of $[Mn(pc3)(H_2O)_2]x.H_2O$ with x ≈ 3.5 , the single crystal structure analysis leads to a formulation of $[Mn(pc3)(H_2O)_2]3.H_2O$, the three water molecules in pores being well located.

IV- Unit cell determination of the dehydrated phase

The unit cell of the dehydrated phase has been tentatively determined using the TREOR program from the XRPD collected at 150°C under nitrogen flux (main text). Despite the poor quality of the pattern, a unit cell which is correlated to the one of the initial compound is found, showing the decreasing of two parameters, a and b, while the c parameter doesn't change.

IV- Adsorption measurements

Adsorption–desorption isotherms of H₂O, CO₂ and NH₃ on **1** were measured at 25 °C using a home-built McBain-type thermobalance. Before measurements, the samples (ca. 15 mg) were outgassed at 180 °C under vacuum (10^{-5} hPa) overnight. Then, measurement of the adsorption branch of the isotherms was started by introducing the gas into the balance, with the pressure increasing incrementally from 0.1 to 30 hPa for H₂O and up to 1000 hPa. After the introduction of each dose of adsorptive, the sample weight was measured continuously until its stabilization. The values of the pressure and weight gain at each equilibrium state were used to construct the adsorption isotherm. Once the highest pressure value had been attained, the desorption branch of the isotherm was measured by progressively decreasing the pressure. The estimated experimental error on the adsorbed amount was about 1 mg g⁻¹. The accuracy of the pressure measurement was 1%, and the temperature was maintained within 1 °C.

CO2 adsorption

Figure S4 : Hypothetical scheme of interaction between CO₂ molecules (gray: C, red: O) and Mn^{2+} (violet) of dimeric units. The sketch is drawn to scale using the following parameters: $d(Mn-Mn) = 3.5 \text{ Å}, r(Mn^{2+}) = 0.72 \text{ Å}, d(C-O) = 1.2 \text{ Å}, r_{VdW}(O) = 1.52 \text{ Å}.$

Figure S5: FTIR spectra of hydrated **1** before (blue) and after adsorption-desorption cycle of CO₂ at 298K (red). The spectra are offset by 0.1 to facilitate comparison.

Figure S6: XRD patterns of hydrated **1** before (blue) and after adsorption-desorption cycle of CO₂ at 298K (red).

In situ PXRD of 1 in the presence of ammonia

The XRD pattern of **1** in the presence of NH₃ was recorded using the *in situ* capillary technique. To realize the measurements **1** was placed in a Pyrex capillary of 0.5 mm external diameter. The capillary was connected to a McBain thermobalance which contained the same sample in the measurement crucible. Given that both samples (inside the capillary and in the measurement crucible) were exposed to the same atmosphere at the same temperature, measuring the weight of one of them gives us the information about the amount of NH₃ adsorbed on the sample placed in the capillary. After outgassing at 180°C under a residual pressure of 10⁻⁵ hPa for 15 h the sample was cooled and exposed to the same atmosphere as the solid in the balance. After attaining 960 hPa the capillary was sealed off and the XRD pattern of the sample was recorded at room temperature using Cu K $\alpha_1\alpha_2$ radiation on a Bruker D8-A25 Discover diffractometer equipped with a LynxEyeXE detector.

Figure S7: Adsorption isotherm of NH₃ on **1** at 298K: full symbols – adsorption, open symbols - desorption.
