Abstract: Depending on the local excess of lanthanide ion ($\text{Ln} = \text{Lu, Yb, Er, Dy, Tb, Gd, Eu, Nd}$) or 2-(tosylamino)-benzylidene-*N*-benzoylhydrazone (H_2L), lanthanide complexes, containing either mono-deprotonated ligand ($\text{Ln}(\text{HL})_2\text{X}$, $\text{X} = \text{Cl, NO}_3$) or both mono- and dideprotonated ligands ($\text{Ln}(\text{L})(\text{HL})$) were preparatively obtained. The crystal structures of $\text{Lu}(\text{HL})_2\text{Cl}$, $\text{Yb}(\text{L})(\text{HL})(\text{H}_2\text{O})_2$, $\text{Yb}(\text{L})(\text{HL})(\text{EtOH})_2(\text{H}_2\text{O})$ and $\text{Er}(\text{L})(\text{HL})$, determined by single crystal diffraction data or from powder diffraction data using Rietveld refinement, have shown the surprising resemblance. The studying of luminescence temperature dependence of $\text{Eu}(\text{HL})_2\text{Cl}$ and $\text{Eu}(\text{L})(\text{HL})$ showed that europium luminescence is quenched by thermally-activated $^5\text{D}_0 \rightarrow \text{T}_1$ energy transfer. The luminescent thermometers based on these complexes demonstrated the sensitivity up to 7.7% at 85K which is the highest value above liquid-nitrogen temperatures obtained to date.

Absorption spectroscopy

Absorption spectra of the lanthanide complexes in DMSO solution were obtained using single-beam spectrophotometer SF-2000 (OKB Spectr) ($l = 10.0$ mm) in the range 250-1000 nm.

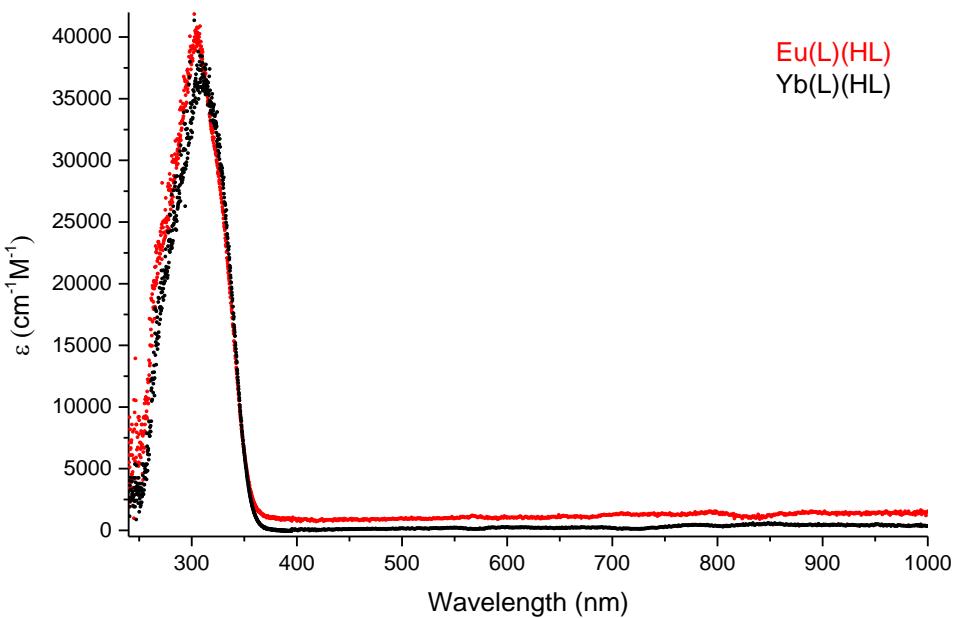

Figure 1 Absorption spectrum of Eu(L)(HL) in DMSO

Diffuse reflection spectroscopy

Diffuse refection spectra were recoded using Perkin Elmer LAMBDA 950 spectrometer in the range 200 – 1150 nm.

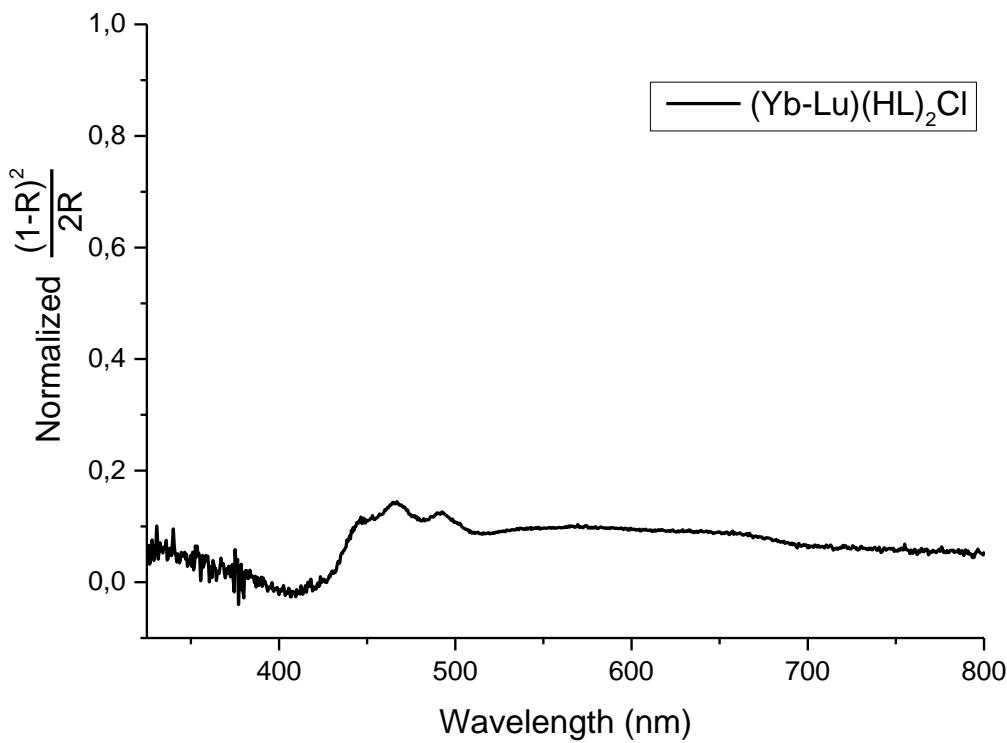

Figure 5 The difference between normalized DR spectra of Yb(HL)₂Cl and Lu(HL)₂Cl

Crystallographic data

The single crystal measurements were performed on Bruker APEX II (Mo radiation) and Bruker APEX II DUO (Cu radiation, microfocus source, used for $\text{Yb}(\text{L})(\text{HL})(\text{EtOH})_2(\text{H}_2\text{O})$) CCD diffractometers. All single crystal structures were solved using SHELXT [1] and refined using SHELXL [2,3].

Structure for $\text{Er}(\text{L})(\text{HL})$ was determined from powder data. The diffraction pattern was collected using $\text{Cu K}\alpha^1$ radiation on a Bruker D8 Advance Vario powder diffractometer equipped with a Ge(111) monochromator and a LynxEye 1D silicon strip detector. The powder pattern was indexed using the SVD-Index algorithm[4] as implemented in TOPAS 5[5]. The structure was solved by Parallel Tempering as implemented in FOX[6] using two rigid bodies with torsions allowed to vary, one corresponding to a free ligand and the other consisting of a ligand linked by two nitrogen atoms to the metal atom. Further refinement was carried out in TOPAS 5, with restraints on all covalent bonds and bond angles between non-metal atoms. A weighting scheme by Toraya[7] with $e=3.5$ was used during refinement for optimal treatment of weaker reflections. The refinement was restraint-consistent[8] with half uncertainty window $\text{HUW}=0.08(4)$ indicating a highly reliable structural model.

The final refined unit cell parameters and refinement indicators for $\text{Er}(\text{L})(\text{HL})$ at $K_1 = 8$ (root mean square deviation from restraints on bond lengths of 0.0054 \AA) are as follows **Ошибка! Источник ссылки не найден.**: $\text{C}_{42}\text{H}_{35}\text{ErN}_6\text{O}_6\text{S}_2$ ($M = 951.16 \text{ g/mol}$): monoclinic, space group $\text{P}2_1/\text{c}$ (no. 14), $a = 18.8998(3) \text{ \AA}$, $b = 9.85077(15) \text{ \AA}$, $c = 25.1072(4) \text{ \AA}$, $\beta = 122.4174(9)^\circ$, $V = 3945.95(11) \text{ \AA}^3$, $R_{wp} = 3.44\%$, $R'_{wp} = 5.10\%$, $R_p = 3.49\%$, $R'_p = 4.31\%$, $R_{\text{Bragg}} = 2.30\%$.

Thermal analysis

Thermal analysis was carried out on a thermoanalyzer STA 409 PC Luxx (NETZSCH, Germany) in the temperature range of 20-1000 °C in argon atmosphere, heating rate 10 °/min.

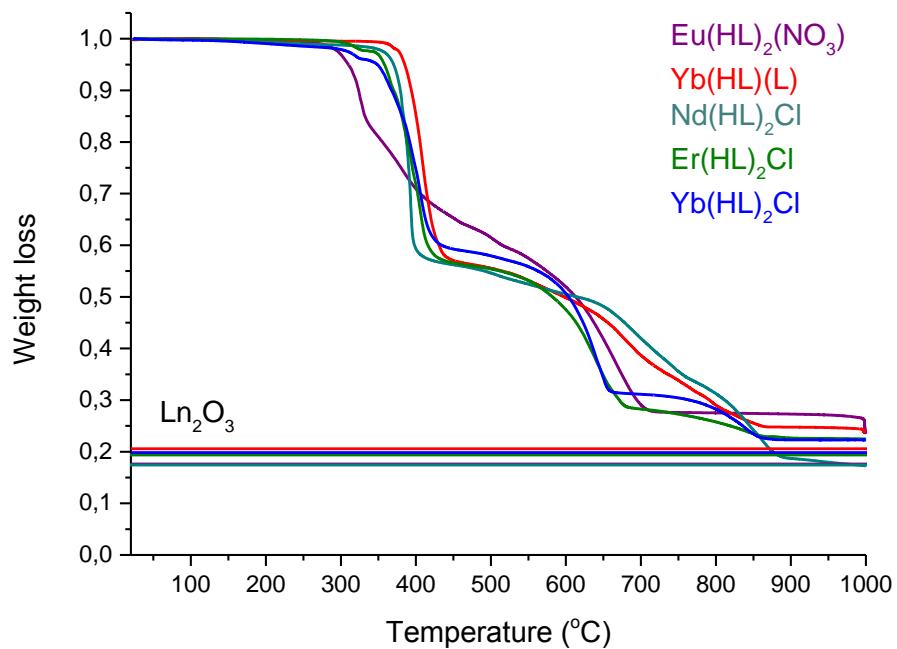

Figure 7 Thermal analysis of the complexes

XRD powder diffraction patterns

X-ray powder diffraction (XRD) measurements were performed on a Rigaku D/MAX 2500 diffractometer in the 2θ range $5\text{--}80^\circ$ with Cu K α radiation ($\lambda = 1.54046 \text{ \AA}$) and on a Bruker D8 Advance diffractometer (Vario geometry) equipped with a Cu K $\alpha 1$ Ge(111) focusing monochromator and a LynxEye one-dimensional position-sensitive detector. The powder X-ray diffraction patterns were indexed using TOPAS 5.0 software.

Integration of europium luminescence

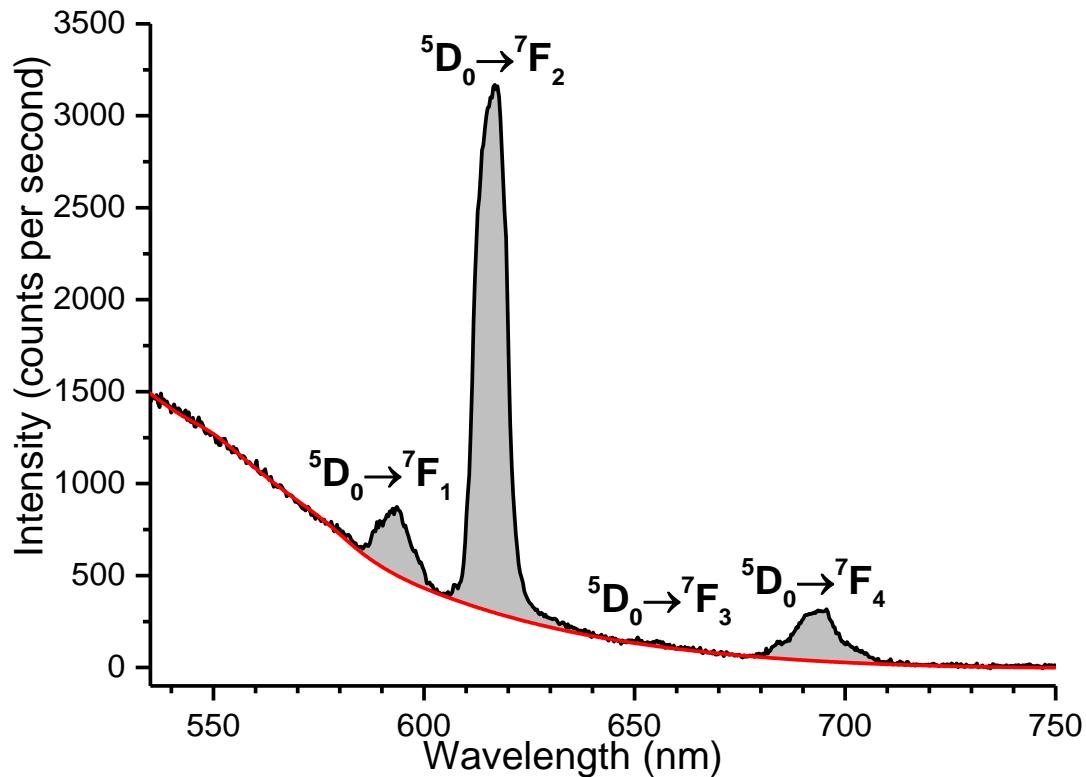

Figure 20 The integration of europium luminescence in the luminescence spectra of $\text{Eu}(\text{HL})_2\text{Cl}$ at 167K. The bold curve is complex luminescence, the red curve is fitting of the organic luminescence.

The organic part of luminescence was fitted with B-spline function. The bands of ${}^5\text{D}_0 \rightarrow {}^7\text{F}_J$ ($J = 1-4$) transitions were integrated with the fitted organic luminescence as a baseline (see Figure 20 as an example) and summarized to give the integrated europium luminescence intensity. The same procedure was run for the spectra of $\text{Eu}(\text{L})(\text{HL})$ in the range 77-200 K and $\text{Eu}(\text{HL})_2\text{Cl}$ in the range 77-240 K, where europium luminesce could still be observed. The integration were made using Origin Pro 9.0 software.

IR spectroscopy

IR spectra in the ATR mode were recorded on a spectrometer SpectrumOne (Perkin-Elmer) in the region of 400-4000 cm⁻¹.

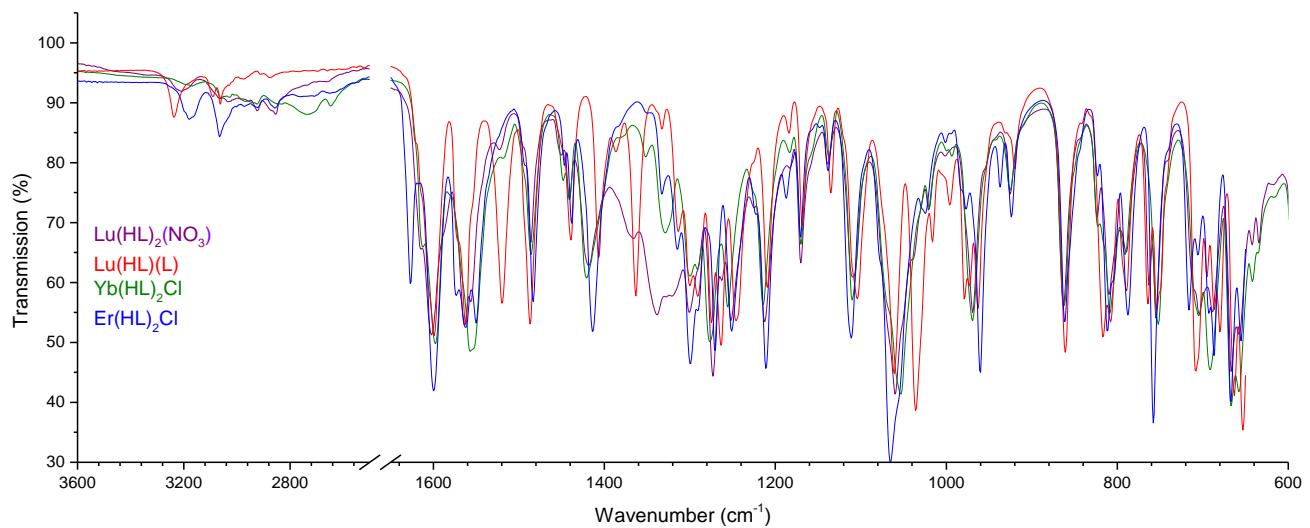

Figure 21 The IR spectra of the complexes

Luminescence spectra with time delay

Luminescence spectra with time delay were measured using Fluorolog 3 spectrofluorometer.

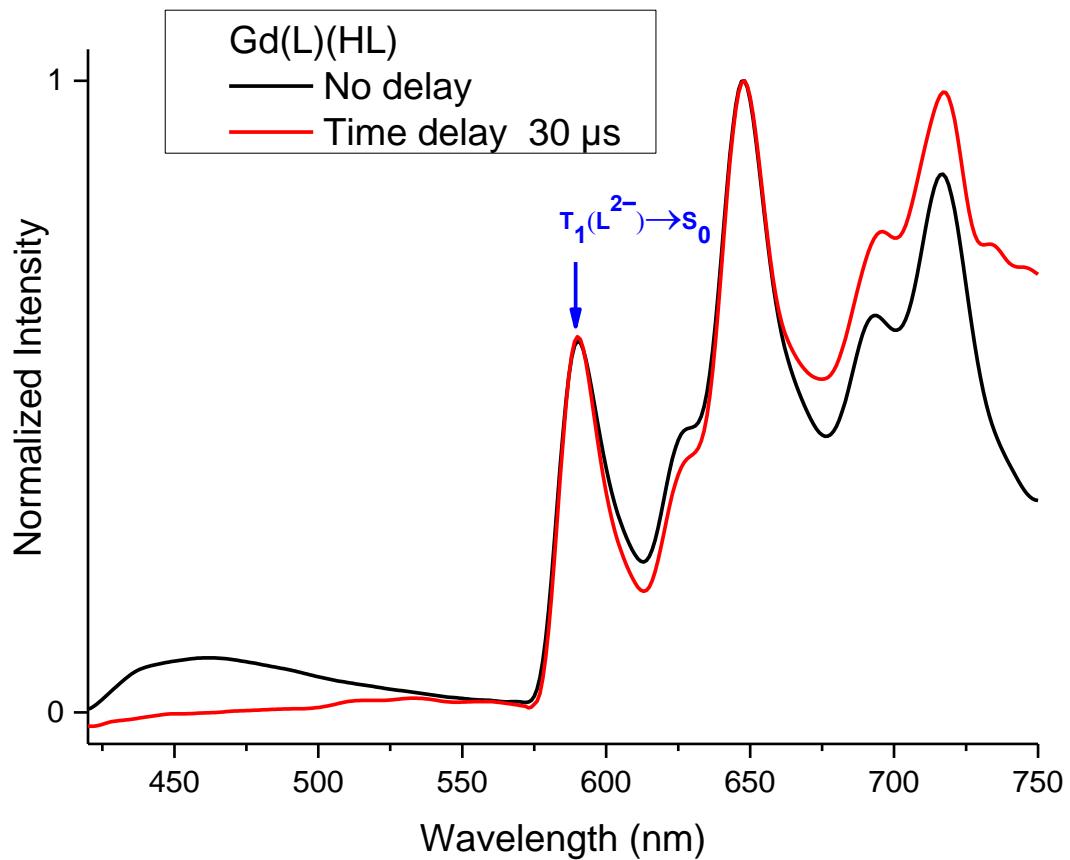

Figure 22 The luminescence spectra of $\text{Gd}(\text{L})(\text{HL})$ in powder at 77K without time delay (black) and with 50 μs time delay (red)

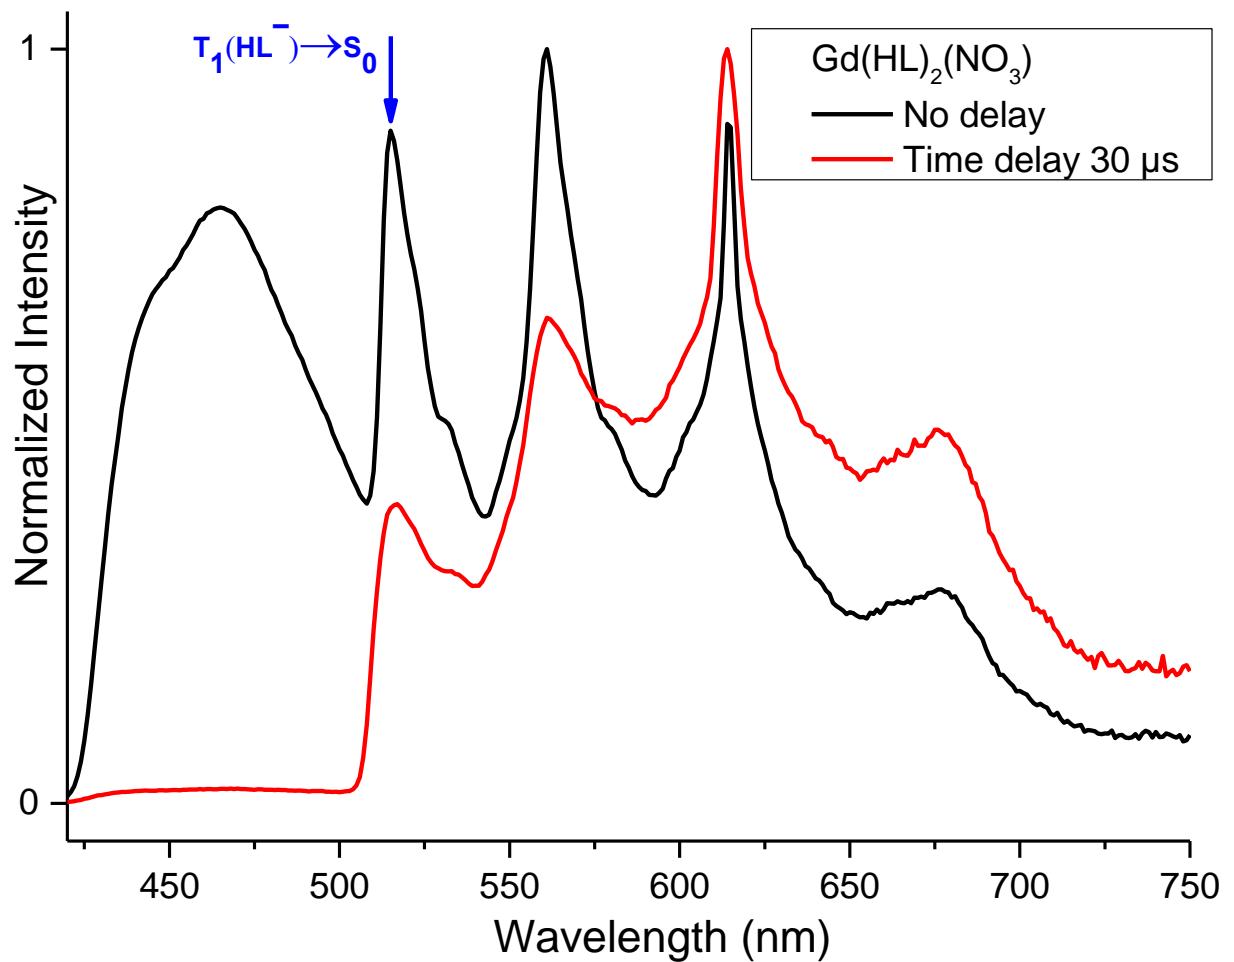

Figure 23 The luminescence spectra of $\text{Gd}(\text{HL})_2(\text{NO}_3)$ in powder at 77K without time delay (black) and with 30 μs time delay (red)

The coordination environment of lanthanide ion

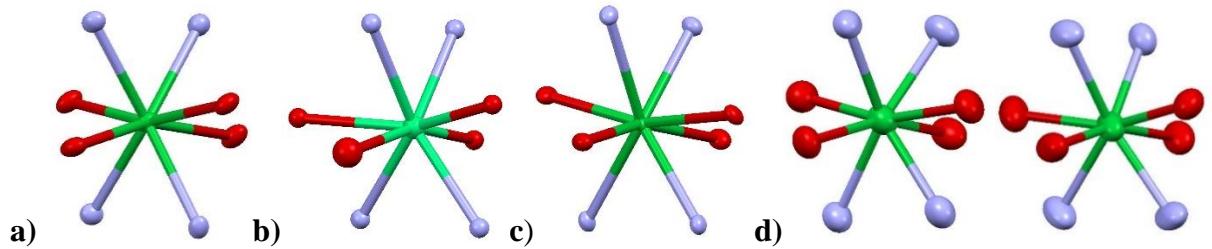

Figure 24 The coordination environment of metal ion in a) Lu(HL)₂Cl, b) Er(L)(HL), c) Yb(L)(HL)(EtOH)₂(H₂O), d) Yb(L)(HL)(H₂O)₂. Oxygen atoms are red, nitrogen atoms are blue.
