### Contents

S1. CD spectra of the enantiomers of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$

S2. Adsorption behavior of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  by clay minerals

S3. Quantum yield of the emission from  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  in various solvents

S4. Emission spectra of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  in clay suspensions

S5. Stereochemical effects of the emission from  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  adsorbed by synthetic saponite

S6. Enhancement of the luminescent quantum yield of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  adsorbed by synthetic saponite

S7. Quenching effects of  $[\text{Ru}(\text{acac})_3]$  on the emission from  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  adsorbed by synthetic saponite

S8. Stern-Volmer plots for the quenching of the emission from  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  by  $[\text{Ru}(\text{acac})_3]$  in methanol

- S9. Stereoselective adsorption of  $[\text{Ru}(\text{acac})_3]$  by an ion-exchange adduct of chiral  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  and synthetic hectorite**
- S10. Comparison of the stereochemical effects on saturated adsorption between  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  and  $[\text{Ru}(\text{phen})_3]^{2+}$**

**S1. CD spectra of the enantiomers of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$**

**Figure S1.** The CD spectra of the enantiomers of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  dissolved in methanol. Solid and dotted curves are for the  $\Delta$ - and  $\Lambda$ -isomers, respectively.

## S2. Adsorption behavior of $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ by clay minerals

### (1) Adsorption amounts versus the added amounts of clay minerals

**Figure S2.** Adsorption amounts of racemic and enantiomeric complexes, when an exfoliated clay mineral was added to a 3:1 (v/v) water/methanol solution containing  $1.0 \times 10^{-4} \text{ M}$  of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$ : (left) sodium montmorillonite (MONT) and (right) synthetic saponite (SAP). The filled and open circles are for the racemic mixture and pure enantiomer, respectively.

### (2) Equilibrium constants of adsorption by clay minerals

The equilibrium constant of adsorption was determined in the following procedure. An ion-exchange adduct of racemic  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  and montmorillonite or synthetic saponite (denoted as Ir(III)/MONT or Ir(III)/SAP, respectively) was dispersed in a 3:1 (v/v) water/methanol. After 6 hours, the dispersion was centrifuged. The concentration of dissociated  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  ions (or Ir(III)) was determined from the UV-vis spectrum of the filtrate. The equilibrium constant of adsorption ( $K_b$ ) was calculated according to the equation below:

$$K_b = [\text{adsorbed Ir(III)}] / \{[\text{dissociated Ir(III)}] [\text{empty sites in a clay mineral}]\}$$

The results are shown in the following table.

**Table S1.** Equilibrium constant of adsorption

clay mineral	[dissociated Ir(III)]/M	[adsorbed Ir(III)]/M	[empty site in a clay mineral]/M	$K_b/\text{M}^{-1}$
MONT	$1.4 \times 10^{-6}$	$4.22 \times 10^{-5}$	$1.4 \times 10^{-6}$	$2.2 \times 10^7$
SAP	$2.4 \times 10^{-6}$	$3.22 \times 10^{-5}$	$5.16 \times 10^{-5}$	$2.6 \times 10^5$

### (3) Improvement of optical purity of partially resolved $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ on adding sodium montmorillonite

The stereochemical effects on adsorption were studied in the following way. Sodium montmorillonite (MONT) was added to a 3:1 (v/v) water/methanol solution containing partially resolved  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$ . After the dispersion was centrifuged, the UV-vis and CD spectra of the filtrate were measured to determine the optical purity of the filtrate. The results were given in the table below. According to them,  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  showed the tendency that it preferred to be adsorbed as a racemic mixture rather than as an enantiomer.

**Table S2.** Improvement of optical purity of partially resolved  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  on adding MONT

	Before adding MONT	After adding MONT
Free $\Lambda$ -isomer/M	$0.97 \times 10^{-5}$	$0.77 \times 10^{-5}$
Free racemic mixture /M	$2.12 \times 10^{-5}$	$1.10 \times 10^{-5}$
optical purity (e.e.)/%	31	41
added MONT/M		$1.24 \times 10^{-5}$
adsorbed $\Lambda$ -isomer/M		$0.97 \times 10^{-5}$
adsorbed racemic mixture /M		$2.12 \times 10^{-5}$
tendency of racemic adsorption ( $\alpha$ )*		1.53

\*The tendency of racemic adsorption ( $\alpha$ ) was estimated according to the following equation:

$$\alpha = \{[\text{adsorbed racemic mixture}]/[\text{free racemic mixture}]\} / \{[\text{adsorbed } \Lambda\text{-isomer}]/[\text{free } \Lambda\text{-isomer}]\}$$

### S3. Quantum yield of the emission from [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> in various solvents

**Table S3.** The peak wavelength and quantum yield of the emission from racemic [Ir(bzq)<sub>2</sub>(phen)](ClO<sub>4</sub>) in various solvents\*

Solvent	Concentration /M	peak wavelength /nm	quantum yield (Q.Y.)
CH <sub>2</sub> Cl <sub>2</sub>	4.4×10 <sup>-5</sup>	571	0.26
CHCl <sub>3</sub>	3.9×10 <sup>-5</sup>	573	0.20
CH <sub>3</sub> OH	3.6×10 <sup>-5</sup>	579	0.09
C <sub>2</sub> H <sub>5</sub> OH	2.7×10 <sup>-5</sup>	576	0.12
CH <sub>3</sub> CN	4.4×10 <sup>-5</sup>	581	0.07
(CH <sub>3</sub> ) <sub>2</sub> CO	3.9×10 <sup>-5</sup>	580	0.08

\*) Quantum yield was calculated according to the following equation:

$$\Phi = \Phi_{st} \left( \frac{A_{st}}{A} \right) \left( \frac{D}{D_{st}} \right) \left( \frac{n^2}{n_{st}^2} \right)$$

where  $\Phi$  is quantum yield (Q.Y.) for an iridium(III) complex,  $A$  absorbance at 430 nm,  $D$  an irradiated area,  $n$  refractive index. The subscript  $st$  means the standard value for [Ru(bpy)<sub>3</sub>]<sup>2+</sup> ( $\Phi_{st} = 0.028$ ). The wavelength of excitation ( $\lambda_{ex}$ ) was 430 nm (ref. K. Nakamaru, *Bull. Chem. Soc. Jpn.*, 1982, **55**, 2697-2705).

#### S4. Emission spectra of $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ in clay suspensions

**Figure S3 (a).** The effects of synthetic saponite (SAP) on the emission spectra of racemic  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$ . A medium was 3:1 (v/v) water/methanol containing  $4.70 \times 10^{-6}$  M of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  and various concentrations of SAP. The concentration of SAP was (a)  $5.0 \times 10^{-5}$ , (b)  $2.5 \times 10^{-5}$ , (c)  $5.0 \times 10^{-6}$ , (d)  $0 \text{ eqL}^{-1}$ , respectively. Excitation wavelength was 430 nm.

**Figure S3 (b).** The effects of sodium montmorillonite (MONT) on the emission spectra of racemic  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$ . A medium was 3:1 (v/v) water/methanol containing  $7.00 \times 10^{-6}$  M of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  and various concentrations of MONT. The concentration of MONT was (a) 0, (b)  $0.44 \times 10^{-5}$ , (c)  $1.10 \times 10^{-5}$ , (d)  $2.20 \times 10^{-5}$ , (e)  $4.40 \times 10^{-5}$  and (f)  $11.0 \times 10^{-5} \text{ eqL}^{-1}$ , respectively. Excitation wavelength was 430 nm.

## S5. Stereochemical effects of the emission from $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ adsorbed by synthetic saponite

**Figure S4** (left). The emission spectra of racemic  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  adsorbed by synthetic saponite (SAP). A medium was (a) 3:1 (v/v) water/methanol containing  $5.00 \times 10^{-6}$  M of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  and  $7.0 \times 10^{-5}$  eqL $^{-1}$  of SAP, (b) dichloromethane, (c) 3:1 (v/v) water/methanol and (d) methanol, respectively. Excitation wavelength was 430 nm

**Figure S4** (right). The emission spectra of  $\Delta$ - (solid) and  $\Lambda$ - (dotted)  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  adsorbed by synthetic saponite (SAP). A medium was (a) 3:1 (v/v) water/methanol containing  $5.00 \times 10^{-6}$  M of  $[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  and  $7.0 \times 10^{-5}$  eqL $^{-1}$  of SAP and (b) 3:1 (v/v) water/methanol, respectively. Excitation wavelength was 430 nm.

## S6. Enhancement of the luminescent quantum yield of [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> adsorbed by synthetic saponite

The quantum yield and the decay life-time were compared for racemic [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> between 1:1 (v/v) water/methanol and 1:1 (v/v) water/methanol/SAP. The obtained quantum yield (Q. Y),  $k_r$  and  $k_{nr}$  are shown in the table below:

Medium	Quantum yield (Q. Y.)( $\Phi$ )	Lifetime / $\mu$ s ( $\tau$ ) at 570 nm	$k_r$ /sec	$k_{nr}$ /sec
1:1(v/v) water/methanol	0.21	0.16	$1.30 \times 10^6$	$4.88 \times 10^6$
1:1(v/v) water/methanol/SAP	0.39	0.37	$1.05 \times 10^6$	$1.65 \times 10^6$

In the above table, the concentration of [Ir(bzq)<sub>2</sub>(phen)](ClO<sub>4</sub>) was  $9.8 \times 10^{-6}$  M at [SAP] =  $1.0 \times 10^{-4}$  eqL<sup>-1</sup>. Quantum yield (Q.Y.) and lifetime were related to  $k_r$  and  $k_{nr}$  as below:

$$\Phi = \frac{k_r}{k_r + k_{nr}}$$

$$\tau = \frac{1}{k_r + k_{nr}}$$

where  $\tau$  is lifetime at 570 nm,  $k_r$  the emissive rate constant and  $k_{nr}$  the non-radiative decay constant, respectively. On the basis of the above results, it was concluded that the enhancement of emission intensity for the clay-chelate hybrid was caused by the lowering of  $k_{nr}$  (or non-radiative decay rate). As stated in the text, it was due to the dehydration of an adsorbed chelate on a clay surface.

**S7. Quenching effects of [Ru(acac)<sub>3</sub>] on the emission from [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> adsorbed by synthetic saponite**

**Figure S5.** The effects of [Ru(acac)<sub>3</sub>] on the emission of [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> adsorbed by synthetic saponite (SAP). The emission spectra were measured in 3:1 (v/v) water/methanol containing [Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup> ( $4.2 \times 10^{-6}$  M) and SAP ( $8.2 \times 10^{-4}$  eqL<sup>-1</sup>): (left)  $\Lambda$ -[Ir(bzq)<sub>2</sub>(phen)]/ $\Lambda$ -[Ru(acac)<sub>3</sub>] and (right)  $\Lambda$ -[Ir(bzq)<sub>2</sub>(phen)]/ $\Lambda$ -[Ru(acac)<sub>3</sub>]. The added concentration of [Ru(acac)<sub>3</sub>] was (a) 0 M, (b)  $1.2 \times 10^{-5}$  M, (c)  $2.4 \times 10^{-5}$  M, (d)  $3.6 \times 10^{-5}$  M, (e)  $4.8 \times 10^{-5}$  M and (f)  $6.0 \times 10^{-5}$  M. Excitation wavelength was 430 nm.

**S8. Stern-Volmer plots for the quenching of the emission from [Ir(bzq)<sub>2</sub>(phen)](ClO<sub>4</sub>) by [Ru(acac)<sub>3</sub>] in methanol.**

**Figure S6.** Stern-Volmer plots for the quenching effect by [Ru(acac)<sub>3</sub>] in methanol. The concentration of [Ir(bzq)<sub>2</sub>(phen)](ClO<sub>4</sub>) was  $4.2 \times 10^{-6}$  M: (triangle)  $\Delta$ -[Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup>/Δ-[Ru(acac)<sub>3</sub>] and (circle)  $\Delta$ -[Ir(bzq)<sub>2</sub>(phen)]<sup>+</sup>/ Δ-[Ru(acac)<sub>3</sub>]. Excitation wavelength was 430 nm.

### S9. Stereoselective adsorption of $[\text{Ru}(\text{acac})_3]$ by an ion-exchange adduct of chiral $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ and synthetic hectorite

$\Delta\text{-}[\text{Ir}(\text{bzq})_2(\text{phen})](\text{ClO}_4)$  ( $1.0 \times 10^{-5}$  mole) was added to a 5 mL of methanol dispersion containing 50 mg of synthetic hectorite (Laporte Inc. Co.; denoted as HEC). The dispersion was centrifuged, leaving a precipitate of an ion-exchange adduct of  $\Delta\text{-}[\text{Ir}(\text{bzq})_2(\text{phen})]^+/\text{HEC}$ . The adduct was dispersed in a 5 mL of methanol solution containing racemic  $2.0 \times 10^{-5}$  mole of  $[\text{Ru}(\text{acac})_3]$ . After being stirred for 1 hour at room temperature, the dispersion was centrifuged. The filtrate (denoted as *F*) was replaced with 5 mL of pure methanol. The dispersion was stirred for 1 hour at room temperature. The filtrate was denoted as *P*. The CD spectra of *F* and *P* were measured and shown below. The results exhibited that *F* and *P* contained the small excesses of  $\Lambda$ - and  $\Delta$ -enantiomers of  $[\text{Ru}(\text{acac})_3]$ , respectively. It implied that  $\Delta\text{-}[\text{Ru}(\text{acac})_3]$  was adsorbed by  $\Delta\text{-}[\text{Ir}(\text{bzq})_2(\text{phen})]^+/\text{HEC}$  more strongly than  $\Lambda\text{-}[\text{Ru}(\text{acac})_3]$ .

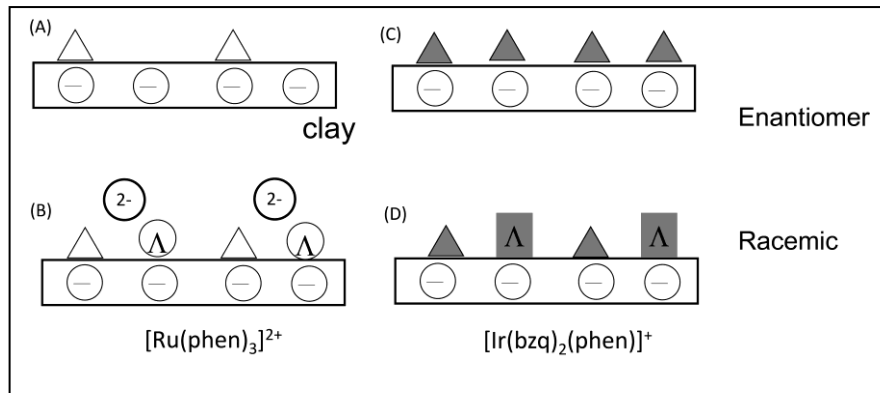

**Figure S7.** The CD spectra of *F* (pink) and *P* (blue). The results showed that *F* and *P* contained  $\Lambda\text{-}[\text{Ru}(\text{acac})_3]$  and  $\Delta\text{-}[\text{Ru}(\text{acac})_3]$  as an excessive enantiomer, respectively.

### S10. Comparison of the stereochemical effects of saturated adsorption between $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ and $[\text{Ru}(\text{phen})_3]^{2+}$

The different behavior between  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  and  $[\text{Ru}(\text{phen})_3]^{2+}$  as to the stereochemical effects on the saturated adsorption amount is rationalized in terms of the balance of the electrostatic repulsion and van der Waals attraction as below:

- 1) In case of  $[\text{Ru}(\text{phen})_3]^{2+}$ , the enantiomer is adsorbed within the CEC of a clay, while the racemic mixture is adsorbed to two times excess of CEC (ref. A. Yamagishi and H. Sato, *Clays and Clay Miner.*, 2012, **60**, 411). The enantiomeric chelate is adsorbed, leaving a vacant space on a surface ((A) in the scheme below), while the racemic chelate is adsorbed, covering fully a clay surface ((B) in the scheme below). The excess adsorption for the racemic case is realized due to the close packing of a racemic pair like a key-and-lock way. In other words, the van der Waals attraction surmounts the electrostatic repulsion between the adsorbed chelates. The enantiomeric chelate is unable to attain such close packing due to the steric hindrance between the ligands.
- 2) In case of  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$ , both the enantiomeric and racemic chelates are adsorbed within the CEC of a clay. They cover fully the surface of a clay surface ((C) and (D) in the scheme below, respectively). The enantiomeric chelate is able to attain such high density, since the electrostatic repulsion between the adsorbed chelates is low due to their monovalent charges.

**Scheme S1.**

- A. The enantiomeric adsorption of divalent  $[\text{Ru}(\text{phen})_3]^{2+}$  within the CEC of a clay layer.
- B. The racemic adsorption of divalent  $[\text{Ru}(\text{phen})_3]^{2+}$  in excess over the CEC of a clay layer. External anions are co-adsorbed to compensate the positive charge.
- C. The enantiomeric adsorption of monovalent  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  within the CEC of a clay.
- D. The racemic adsorption of monovalent  $[\text{Ir}(\text{bzq})_2(\text{phen})]^+$  within the CEC of a clay.
