#### **Table of Contents**

- S1. Raman spectra of products obtained from ball-milling a mixture of pristine g-C<sub>3</sub>N<sub>4</sub> and C<sub>60</sub> with and without LiOH catalyst.**
- S2. High-resolution C1s, N1s and O1s XPS spectra.**
- S3. XRD patterns of products obtained from ball-milling a mixture of pristine g-C<sub>3</sub>N<sub>4</sub> and C<sub>60</sub> with and without LiOH catalyst.**
- S4. TGA curves.**
- S5. Schematic illustration of the formation mechanism of the g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S6. FTIR, Raman spectra and XRD patterns of product obtained by reaction of g-C<sub>3</sub>N<sub>4</sub> with C<sub>60</sub> in DMF solution.**
- S7. SEM image of product obtained from ball-milling pure g-C<sub>3</sub>N<sub>4</sub>.**
- S8. TEM elemental mapping images of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S9. Quantum efficiency and action spectra of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S10. Typical time courses of H<sub>2</sub> production based on pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S11. Visible light photocatalytic H<sub>2</sub> production rates of different control samples.**
- S12. Diffuse reflectance UV-vis absorption spectra of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S13. BET surface areas of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid calculated from the nitrogen adsorption-desorption isotherms.**
- S14. Electrical conductivities of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S15. Mott–Schottky plots of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**
- S16. PL spectra of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**

**S1. Raman spectra of products obtained from ball-milling a mixture of pristine  $g\text{-C}_3\text{N}_4$  and  $\text{C}_{60}$  with and without LiOH catalyst.**

**Figure S1.** Raman spectra of pristine  $g\text{-C}_3\text{N}_4$  (a), products obtained from ball-milling a mixture of pristine  $g\text{-C}_3\text{N}_4$  and  $\text{C}_{60}$  without (b) and with (c) LiOH catalyst, and pristine  $\text{C}_{60}$  (d). The excitation laser light wavelengths are 532 nm (A) and 785 nm (B), respectively.

**S2. High-resolution C1s, N1s and O1s XPS spectra.**

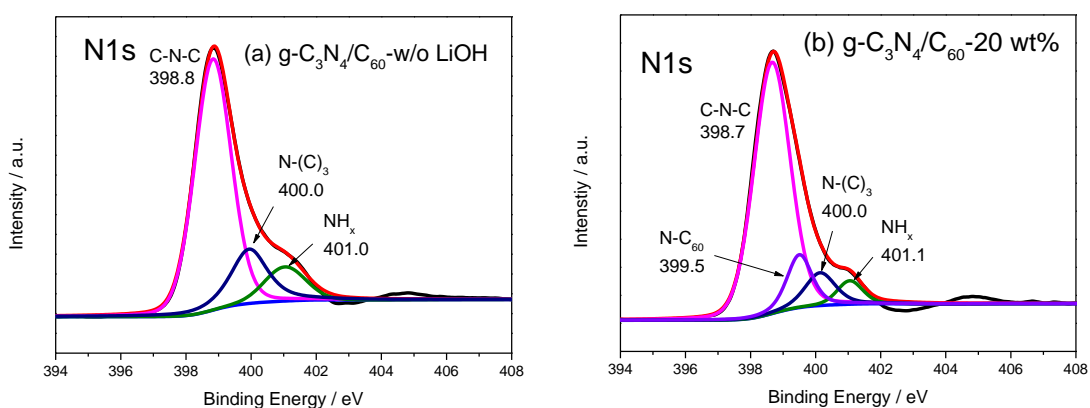

**Figure S2.** High-resolution C1s XPS spectra of  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -4 wt% (a) and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -20 wt% (b).

**Figure S3.** High-resolution N1s XPS spectra of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-4 wt% (a) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-20 wt% (b).

**Figure S4.** High-resolution O1s XPS spectra of pristine g-C<sub>3</sub>N<sub>4</sub> (a) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% (b).

**Figure S5.** High-resolution N1s XPS spectra of products obtained from ball-milling a mixture of pristine g-C<sub>3</sub>N<sub>4</sub> and C<sub>60</sub> without (a) and with (b) LiOH catalyst.

**S3. XRD patterns of products obtained from ball-milling a mixture of pristine g-C<sub>3</sub>N<sub>4</sub> and C<sub>60</sub> with and without LiOH catalyst.**

**Figure S6.** XRD patterns of pristine g-C<sub>3</sub>N<sub>4</sub> (a), products obtained from ball-milling a mixture of pristine g-C<sub>3</sub>N<sub>4</sub> and C<sub>60</sub> without (b) and with (c) LiOH catalyst, and pristine C<sub>60</sub> (d).

**S4. TGA curves.**

**Figure S7.** TGA curves of pristine g-C<sub>3</sub>N<sub>4</sub> (a), g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid (b), and C<sub>60</sub> (c). The right dotted vertical line was added to aid identifying the last weight loss step (708 - 830 °C) corresponding to the decomposition of C<sub>60</sub>.

**Figure S8.** TGA curves of pristine  $g\text{-C}_3\text{N}_4$  (a), pure  $g\text{-C}_3\text{N}_4$  after ball-milling (BM- $g\text{-C}_3\text{N}_4$ , b), products obtained from ball-milling a mixture of pristine  $g\text{-C}_3\text{N}_4$  and  $\text{C}_{60}$  without (c) and with (d) LiOH catalyst.

**S5. Schematic illustration of the formation mechanism of the  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  hybrid.**

**Scheme S1.** A schematic illustration of the formation mechanism of the  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  hybrid via the mechanochemical ball-milling in the existence of LiOH as catalyst.

**S6. FTIR, Raman spectra and XRD patterns of product obtained by reaction of g-C<sub>3</sub>N<sub>4</sub> with C<sub>60</sub> in DMF solution.**

**Figure S9.** FTIR spectra (A), Raman spectra (B) and XRD patterns (C) of pristine g-C<sub>3</sub>N<sub>4</sub> (a), C<sub>60</sub> (b) and product obtained by reaction of g-C<sub>3</sub>N<sub>4</sub> with C<sub>60</sub> in DMF solution (g-C<sub>3</sub>N<sub>4</sub>-C<sub>60</sub>, c).

A mixture of 200 mg pristine g-C<sub>3</sub>N<sub>4</sub> and 200 mg C<sub>60</sub> was dispersed in N,N-dimethylformamide (DMF) solution and stirred for 24 h under 70 °C, followed by Soxhlet-extraction with CS<sub>2</sub> for 48 h to remove the unreacted C<sub>60</sub>. No C<sub>60</sub> moiety was detected in the final product based on FTIR, Raman and XRD characterizations, revealing that the reaction of C<sub>60</sub> with the terminal NH<sub>x</sub> did not occur despite of the high nucleophilicity of the primary amine, and consequently covalent bonding of C<sub>60</sub> with the terminal NH<sub>x</sub> at the edge of pristine g-C<sub>3</sub>N<sub>4</sub> seems unlikely.

**S7. SEM image of product obtained from ball-milling pure g-C<sub>3</sub>N<sub>4</sub>.**

**Figure S10.** SEM image of product obtained from ball-milling of pure g-C<sub>3</sub>N<sub>4</sub>.

**S8. TEM elemental mapping images of g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**

**Figure S11.** TEM elemental mapping images of the portion selected for pristine g-C<sub>3</sub>N<sub>4</sub> (a, c, e) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid (b, d, f). The corresponding C (c, d) and N (e, f) elemental mapping images are also shown.

The C elemental mapping image of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid (image d) shows the enrichment of C elements at the edges (marked by arrows), whereas such a phenomenon is not observed for N element in the N elemental mapping image of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid (image f). For the case of pristine g-C<sub>3</sub>N<sub>4</sub>, both C and N elements distribute uniformly without obvious enrichment at the edges (images c and e). This provides further experimental evidence on the C<sub>60</sub> bonding to the cleaved edge of g-C<sub>3</sub>N<sub>4</sub>.

### S9. Quantum efficiency and action spectra of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.

To measure the quantum yield for visible light H<sub>2</sub> evolution, 50 mg powder sample was dispersed in 100 mL aqueous solution containing 17.5 mg Eosin Y (EY) and 5 mL triethanolamine (TEOA), which was irradiated by a monochromatic light using a bandpass filter ( $\pm 5$  nm) for 420, 450, 475, 520, and 550 nm, respectively. The quantum efficiency ( $\Phi$ ) is calculated according to the following equation (1):

$$\begin{aligned}\Phi &= \frac{\text{number of reacted electrons}}{\text{number of incident photons}} \times 100\% \\ &= \frac{\text{number of evolved H}_2 \text{ molecules} \times 2}{\text{number of incident photons}} \times 100\%\end{aligned}\quad (1)$$

Where the number of incident photons ( $N_{\text{ph}}$ ) can be calculated from the power of the incident light ( $P_{\text{ph}}$ , 0.194, 0.205, 0.202, 0.305 and 0.225 J/s for 420, 450, 475, 520, and 550 nm, respectively), which was calibrated by an irradiatometer (FZ-A, Beijing Normal University Optical Instrument), according to equation (2) (see Figure S12):

$$N_{\text{ph}} = P_{\text{ph}} \times t / (hc/\lambda) = P_{\text{ph}} \times t \times \lambda / (hc) \quad (2)$$

Where  $t$  is the irradiation time,  $\lambda$  is the wavelength of the incident light,  $h$  is planck constant,  $c$  is the speed of light in vacuum.

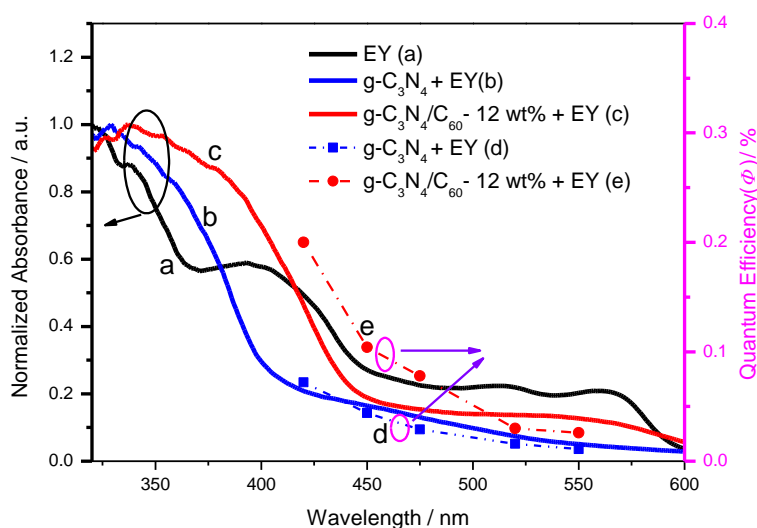

**Table S1.** Quantum efficiencies ( $\Phi$ ) of different samples with (w) or without (w/o) Pt cocatalyst and EY photosensitizer measured under irradiation with visible light at  $\lambda = 420$  nm.

sample	condition		quantum efficiency ( $\Phi$ )
	Pt (0.3 wt%)	EY (35 wt%)	
pristine g-C <sub>3</sub> N <sub>4</sub>	w/o	w	0.072%
g-C <sub>3</sub> N <sub>4</sub> /C <sub>60</sub> -12 wt%	w/o	w	0.20%
no (control)	w	w	6.95%
pristine g-C <sub>3</sub> N <sub>4</sub>	w	w	6.79%
g-C <sub>3</sub> N <sub>4</sub> /C <sub>60</sub> -12 wt%	w	w	6.97%
pristine g-C <sub>3</sub> N <sub>4</sub>	w	w/o	0.037%
g-C <sub>3</sub> N <sub>4</sub> /C <sub>60</sub> -12 wt%	w	w/o	0.051%

Without the existence of Pt cocatalyst,  $\Phi$  of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid is 0.20% (with the existence of EY photosensitizer), which is about 2.8 times of that for pristine g-C<sub>3</sub>N<sub>4</sub> (0.072%). Such an enhancement ratio is consistent with that measured for H<sub>2</sub> production rate (about 4.0 times), confirming that covalently bonding of C<sub>60</sub> onto g-C<sub>3</sub>N<sub>4</sub> can indeed result in enhanced visible light photocatalytic H<sub>2</sub> production.

We also measured and compared the quantum efficiencies ( $\Phi$ ) of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid and pristine g-C<sub>3</sub>N<sub>4</sub> under different conditions with the existence of Pt cocatalyst (measured under irradiation with visible light at  $\lambda = 420$  nm). Surprisingly, with the co-existence of both Pt cocatalyst and EY photosensitizer, the measured  $\Phi$  of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid and pristine g-C<sub>3</sub>N<sub>4</sub> (6.97% and 6.79%, respectively) are quite comparable to that obtained for the control sample (only Pt cocatalyst + EY photosensitizer, 6.95%). This suggests that in this case the visible light H<sub>2</sub> production is primarily contributed by EY. Furthermore, without the existence of EY photosensitizer, the measured  $\Phi$  of g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid and pristine g-C<sub>3</sub>N<sub>4</sub> (0.051% and 0.037%, respectively) with the existence of Pt cocatalyst only dramatically decrease, and are even lower than that measured without Pt cocatalyst (0.072%). This confirms further the importance of EY photosensitizer which plays the role of sensitizer for extending the spectral response region as discussed already in the main text.

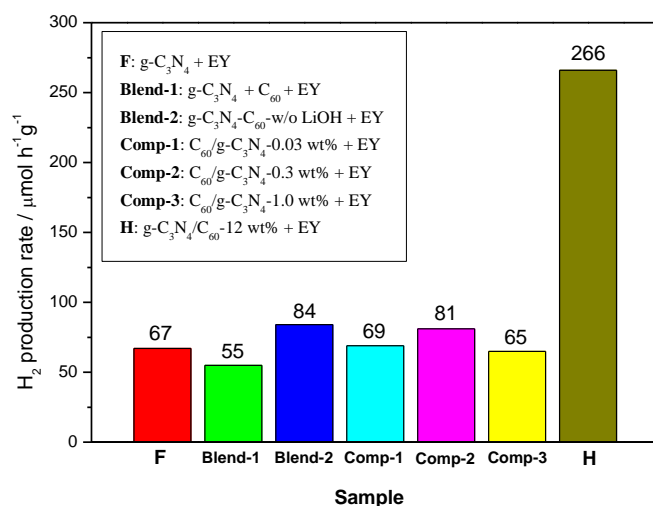

**Figure S12.** UV-VIS diffuse reflectance spectra of EY (a), g-C<sub>3</sub>N<sub>4</sub>+EY (b) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt%+EY (c), and action spectra for H<sub>2</sub> evolution of g-C<sub>3</sub>N<sub>4</sub>+EY (d) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt%+EY (e) from an aqueous triethanolamine (TEOA) solution under visible light irradiation of 300 W Xe-lamp using a bandpass filter for 420, 450, 475, 520, and 550 nm, respectively.

**S10. Typical time courses of  $H_2$  production based on pristine  $g-C_3N_4$  and  $g-C_3N_4/C_{60}$ -12 wt% hybrid.**

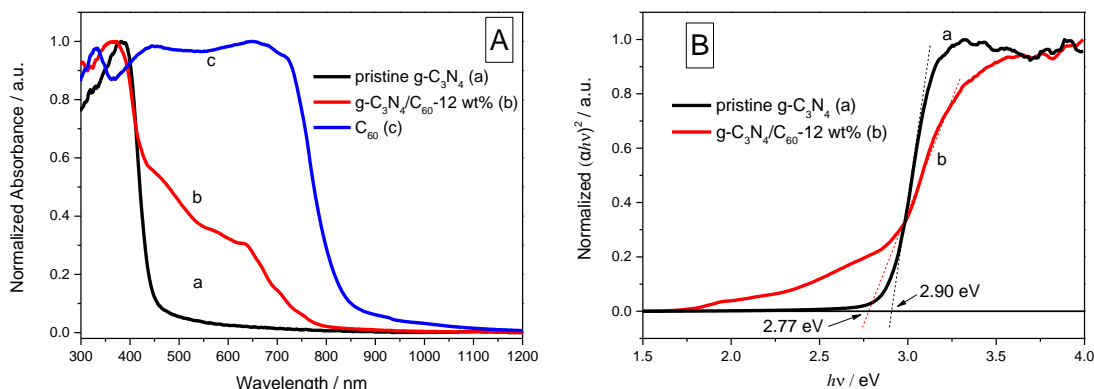

**Figure S13.** Typical time courses of  $H_2$  production based on pristine  $g-C_3N_4$  and  $g-C_3N_4/C_{60}$ -12 wt% hybrid. The measurements were carried out in an aqueous solution (containing TEOA as a hole scavenger and EY as the photosensitizer) evacuated per 3 h without renewing the hole scavenger under visible light ( $\lambda > 420$  nm) irradiation of 300 W Xe-lamp.

**S11. Visible light photocatalytic  $H_2$  production rates of different control samples.**

**Figure S14.** Photocatalytic  $H_2$  production rates of different samples measured in 5 vol% TEOA aqueous solution in the presence of EY for 3 h under visible light ( $\lambda > 420$  nm) irradiation of 300 W Xe-lamp. **Blend-1:** a physical blend of  $g-C_3N_4/C_{60}$  (64:9, w/w); **Blend-2:** a mixture of pristine  $g-C_3N_4$  and  $C_{60}$  powders ball-milled without LiOH catalyst ( $g-C_3N_4-C_{60}$ -w/o LiOH). **Comp-1, 2, 3:**  $C_{60}/g-C_3N_4$  composites with different  $C_{60}/\text{dicyandiamide}$  mass ratios (0.03 wt%, 0.3 wt% and 1.0 wt% for **Comp-1, 2, 3**, respectively) using the method reported in ref. [27].

**S12. Diffuse reflectance UV-vis absorption spectra of pristine  $g\text{-C}_3\text{N}_4$  and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -12 wt% hybrid.**

**Figure S15.** Diffuse reflectance UV-vis absorption spectra (A) and  $(\alpha h\nu)^2$  versus  $h\nu$  curves (B) of pristine  $g\text{-C}_3\text{N}_4$  (a) and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -12 wt% hybrid (b), and  $\text{C}_{60}$  (c).

**S13. BET surface areas of pristine  $g\text{-C}_3\text{N}_4$  and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  hybrid calculated from the nitrogen adsorption-desorption isotherms.**

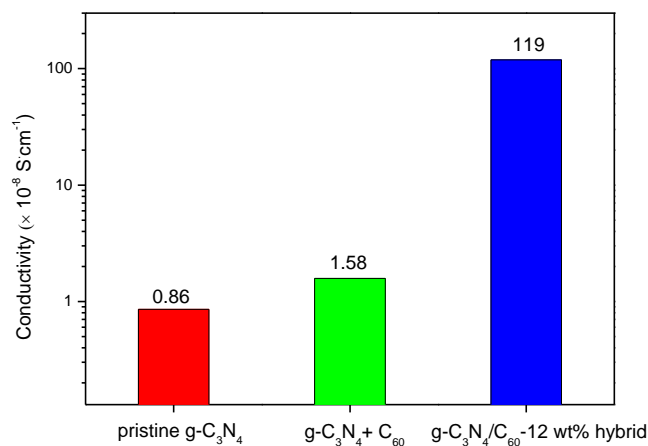

**Table S2.** BET surface areas of pristine  $g\text{-C}_3\text{N}_4$ , BM- $g\text{-C}_3\text{N}_4$ ,  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -12 wt% and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  w/o LiOH.

sample	BET Surface area ( $\text{m}^2/\text{g}$ )
pristine $g\text{-C}_3\text{N}_4$	12.5
BM- $g\text{-C}_3\text{N}_4$	16.1
$g\text{-C}_3\text{N}_4/\text{C}_{60}$ -12 wt%	16.6
$g\text{-C}_3\text{N}_4\text{-C}_{60}$ -w/o LiOH	16.9

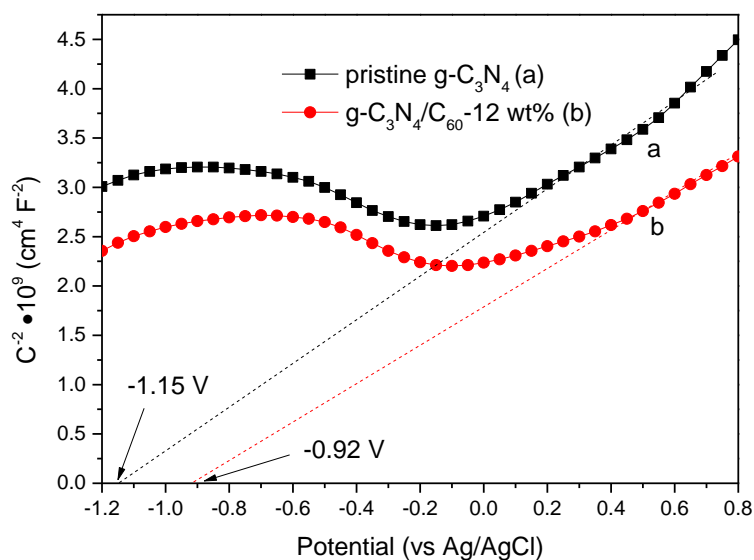

**Figure S16.** Nitrogen adsorption-desorption isotherms of  $g\text{-C}_3\text{N}_4$  (a) and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  hybrid (b).

**S14. Electrical Conductivities of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**

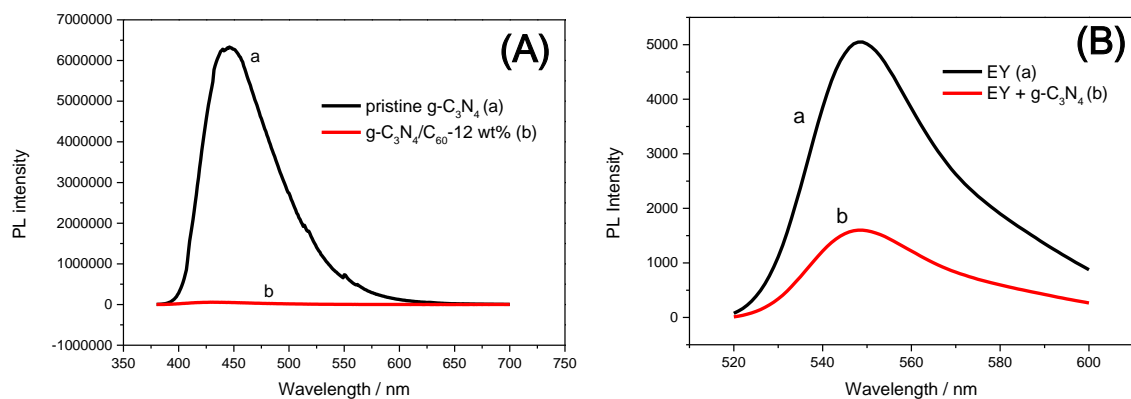

**Figure S17.** Electrical conductivities of the pristine g-C<sub>3</sub>N<sub>4</sub>, g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% and a physical blend of g-C<sub>3</sub>N<sub>4</sub>:C<sub>60</sub> (g-C<sub>3</sub>N<sub>4</sub> + C<sub>60</sub>). Samples were pressed into tablets with the same thickness of approximately 1 mm.

**S15. Mott–Schottky plots of pristine g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub> hybrid.**

**Figure S18.** Mott-Schottky (MS) plots of pristine g-C<sub>3</sub>N<sub>4</sub> (a) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid (b) film electrodes. The MS plots were obtained in a 0.1 M Na<sub>2</sub>SO<sub>4</sub> aqueous solution at a frequency of 1 kHz. The flat band potentials of g-C<sub>3</sub>N<sub>4</sub> (a) and g-C<sub>3</sub>N<sub>4</sub>/C<sub>60</sub>-12 wt% hybrid (b) are determined to be -1.15 and -0.92 V vs. Ag/AgCl, which correspond to -0.95 and -0.72 V vs. NHE, respectively, according to an equation  $E(\text{NHE}) = E(\text{Ag/AgCl}) + 0.198$ .

**S16. PL spectra of pristine  $g\text{-C}_3\text{N}_4$  and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$  hybrid.**

**Figure S19.** (A) PL spectra of pristine  $g\text{-C}_3\text{N}_4$  (a) and  $g\text{-C}_3\text{N}_4/\text{C}_{60}$ -12 wt% hybrid (b) under the excitation wavelength of 360 nm. (B) PL spectra of EY (a) and EY +  $g\text{-C}_3\text{N}_4$  (b) under the excitation wavelength of 520 nm.
