${ }^{a}$ The observation of two relatively broad peaks with a 1:1 ratio for carbons C12 and C13 is attributed to the fact that ranitidine exists as a 1:1 mixture of $E$ or $Z$ isomers, depending on the orientation of the nitroethylenediamine group. ${ }^{31}$ The exchange between these two isomers is in the slow regime in the ${ }^{13} \mathrm{C} N M R$ timescale, while it is in the intermediate regime in the ${ }^{1} \mathrm{H}$ NMR timescale leading to very broad signals for H12 and H17 in the ${ }^{1} \mathrm{H}$ NMR spectrum. No signal for H18 is observed and C18 is observed as a 1:1:1 triplet with a 28.5 Hz separation, which suggests the substitution of H 18 by a deuterium atom from $D_{2} \mathrm{O}$, used as solvent in NMR measurement
