## Quantum Theory of Atoms in Molecules

The use of critical point (CP) analysis as a means to describe the structure of an evolving charge density,  $\rho$ , was first articulated by Bader as part of his Quantum Theory of Atoms in Molecules (QTAIM).<sup>1,2</sup> Central to this theory is a representation of the charge density in terms of the elements of its critical set. The CPs are the zero-dimensional elements of this set and coincide with points where the gradient of the charge density,  $\nabla\rho$ , vanishes. There are four types of CPs classified by the eigenvalues of the Hessian of  $\rho$  at the CP. CPs of saddle character with two negative curvatures (bond CPs) and one-dimensional lines (bond paths) are associated with bonding interactions. Ring CPs are saddle points with one negative curvature and occur inside rings of bond paths, such as inside a benzene ring. Cage

CPs, minima in  $\rho$ , exist inside cages of atoms connected by bond paths, such as in fullerene. Two dimensional surfaces of zero-flux in the gradient of the charge density,  $\nabla\rho$ , surrounding nuclear CPs (maxima) delineate the boundaries of individual atoms in molecules. Atoms in molecules, or atomic basins, are three-dimensional structures with well-defined energies and properties that depend on the energy.

Among the properties associated with an atom is its Bader charge, defined as the difference between the integrated electron density over an atomic basin and the atom's atomic number. There are many methods for calculating atomic charges with some common choices being Mulliken,<sup>3,4</sup> Hirshfeld,<sup>5</sup> and natural population analysis (NPA).<sup>6</sup> We choose to only report Bader charges in this work due to the focus on the electron charge density. Methods such as Mulliken charges and NPA rely on wavefunctions and are often highly basis set dependent. Hirshfeld charges are based on the charge density, but require a promolecular charge density for comparison. Bader charges are based only on the topology and geometry of the charge density of the molecule in question. For a useful review, see Ref. 7.

## Residues in Each Size Model

Table S1: Amino acid residues and metal ions included in active site models from the three QM/DMD configurations and total number of residues and atoms for each configuration for the 7Å model.

	Config. 1	Config. 2	Config. 3
3Å system	Asp178	Asp178	Asp178
	His180	His180	His180
	Asp267	Asp267	Asp267
	Zn <sup>2+</sup>	Zn <sup>2+</sup>	Zn <sup>2+</sup>
4Å system	Substrate	Substrate	Substrate
	Leu179	Leu179	Leu179
	Gly304	Tyr306	Tyr306
5Å system	Tyr306		
	His 142	His142	His142
	His143	His143	His143
6Å system	Gln263	Gly304	Gly304
	Gly265	Gly303	Gly303
	Met274		
7Å system	Gly303		
	Gly305		
	Ala266	Cys153	Cys153
Residues	Thr268	His181	His181
	His181	Pro209	Pro209
	Phe207	Gly265	Gly265
	Phe208	Ala266	Ala266
	Gly151	Thr268	Thr268
	Phe152	Met274	Met274
	Asp176	Gly305	Gly305
	K <sup>+</sup>	K <sup>+</sup>

## Topology of Active Site for Three Nuclear Configurations

The topology of the charge density in the central region of HDAC8 varies depending on the nuclear coordinates chosen from QM/DMD simulations. The bond paths and critical points in the central region for the three lowest energy configurations studied are shown in

Figure S1. The lowest energy coordinates, configuration 1, possess a bond path between the carbonyl carbon (C1) and the water oxygen (Ow), which also necessitates the existence of a ring CP. This bond path is not present in configurations 2 or 3.

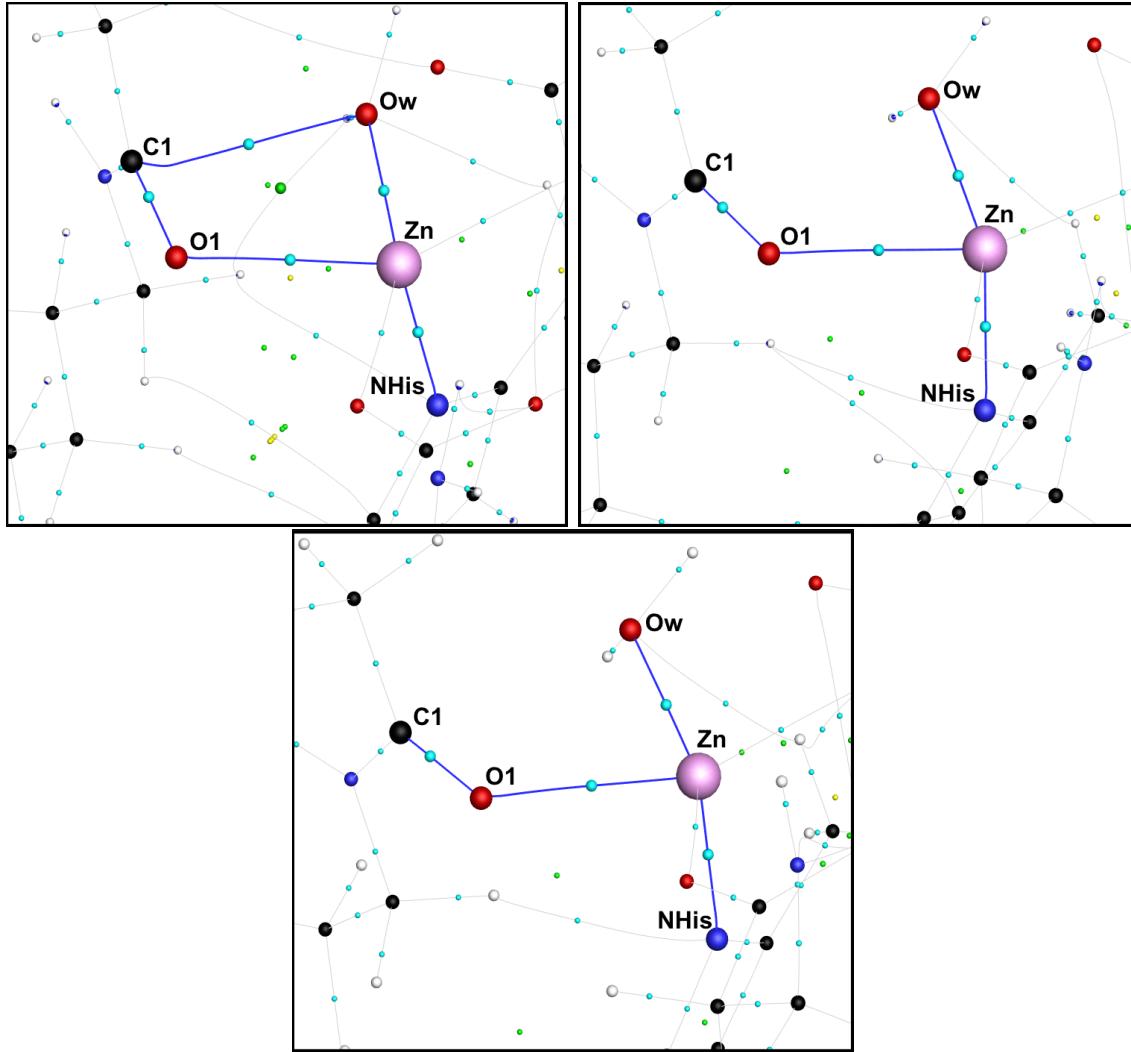

Figure S1: Topology in the central region of HDAC8 for configuration 1 (top left), 2 (top right), and 3 (bottom). Bond CPs are shown in cyan and ring CPs in green.

## Bader Atomic Charges

In general, atomic charges do not vary much as the basis set switches from DZP to TZP, but the functional choice can make a difference in the charges. Even the relative differences

between charges for different atoms are dependent on functional choice in some cases. For example, Using an LDA functional, the Ow charge is lower than the O1 charge for system sizes between 5–7 Å but for the M06L functional the configuration 1 and configuration 2 Ow charge is similar to O1. However, most of the trends of atomic charges are consistent as system size increases.

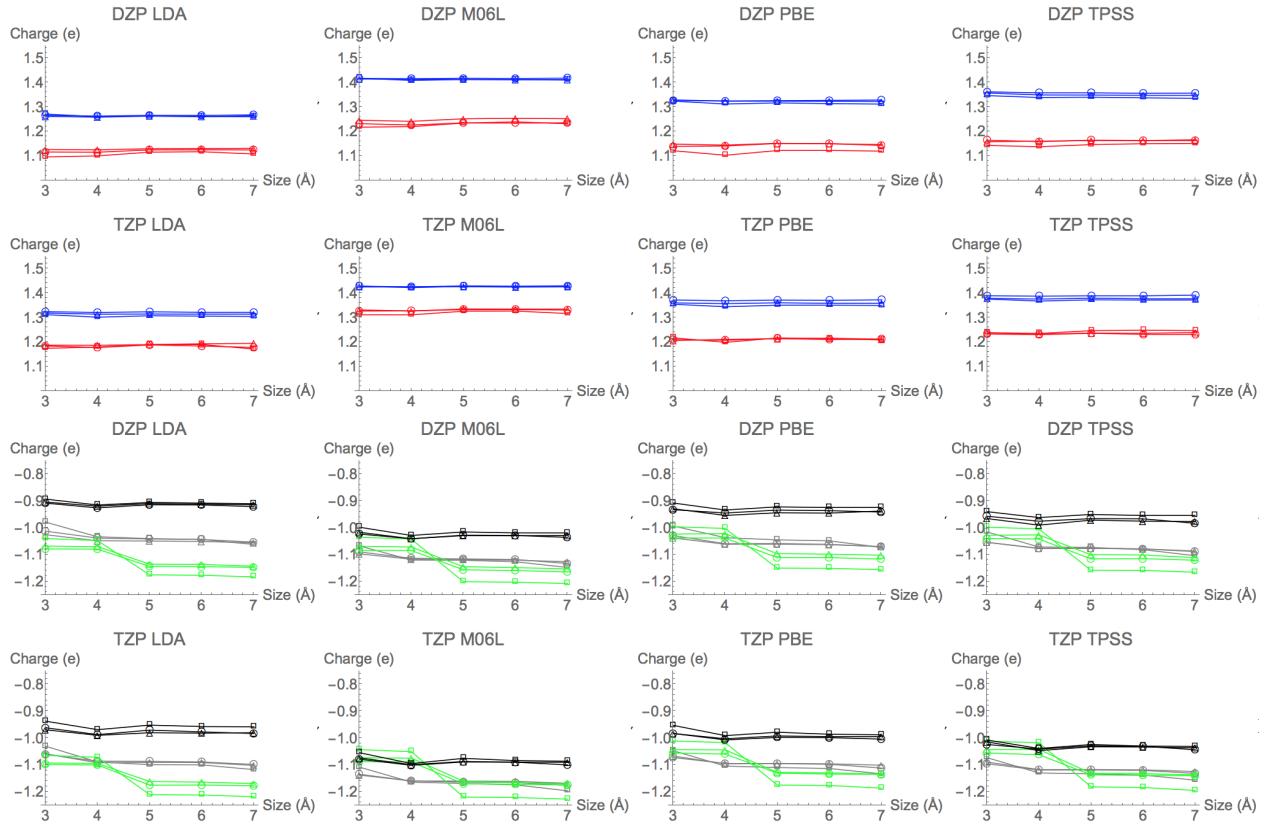

Figure S2: Bader atomic charges for Zn<sup>2+</sup> (blue), C1 (red), O1 (grey), Ow (green), and NH<sub>3</sub> (black). Each plot shows results for one calculation method as active site model sizes increase from 3–7 Å. The three lines for each atom on each plot represent the three different starting QM/DMD configurations used with the following shapes: configuration 1-square, 2-circle, 3-triangle.

## Bader Atomic Volumes

The volumes of Bader atomic basins using a cut-off of  $\rho = 0.001$  for nuclear configuration 1 are displayed in Figure S3. Volumes for Ow and O1 initially decrease as the system size

modeled increases to 4 and 5 Å. This is due to the full residue sphere being added to the truncated protein model around these atoms, which drastically reduces their volumes. Once the 5 Å system size is reached, the volumes of the five atomic basins mostly change inversely to the atomic charges presented in the main text (bottom of Figure S3). This is expected, as a lower charge means more electrons are added to the atomic basin, resulting in a larger volume. As with atomic charges, the volumes of atoms are mostly converged at the 5 Å model size, except for O1 and Ow.

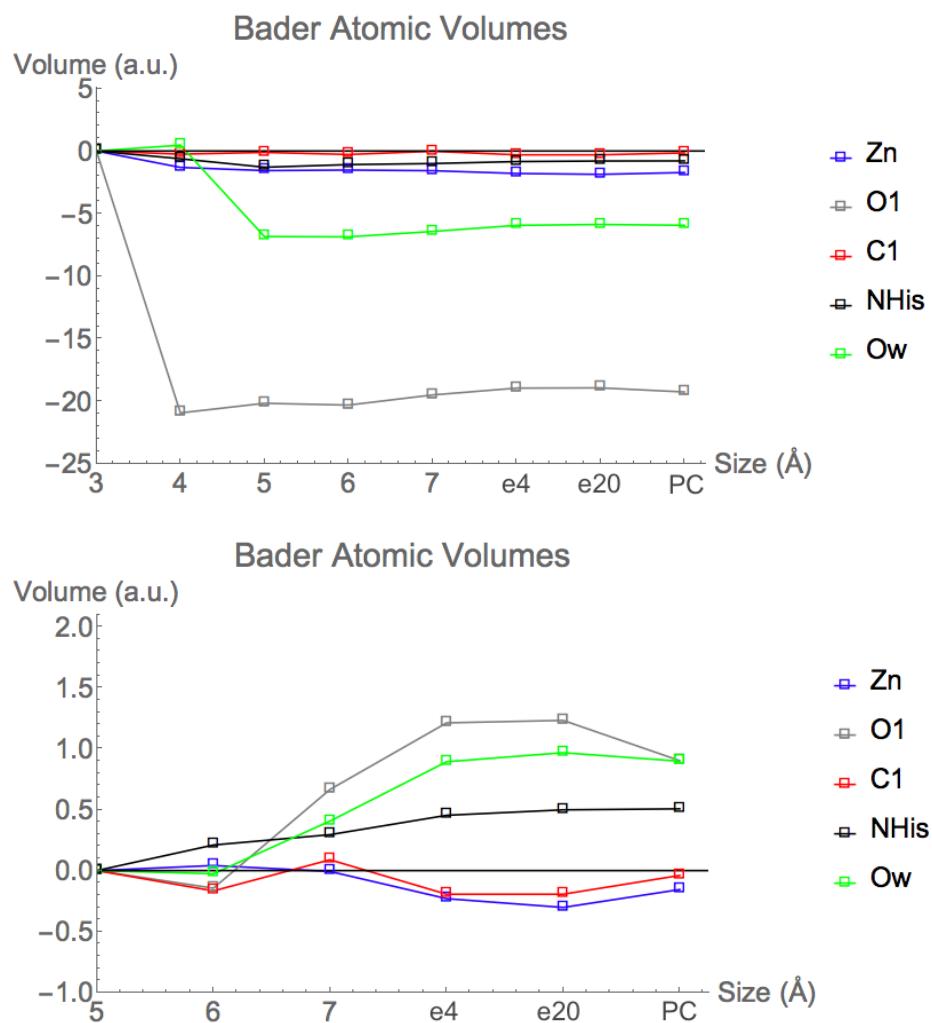

Figure S3: Bader atomic volumes for  $\text{Zn}^{2+}$ , O1, C1, NHis, and Ow using the coordinates from nuclear configuration 1. The bottom figure shows the deviation in volume for each atom from the 5 Å system atom volumes—once a full residue sphere is included around the five atoms tested.

## Magnitude of $\rho$ at CPs

There are small variations in the amount of charge density at critical points based on method choice, but the trends as system size increases are consistent across all functionals and basis sets.

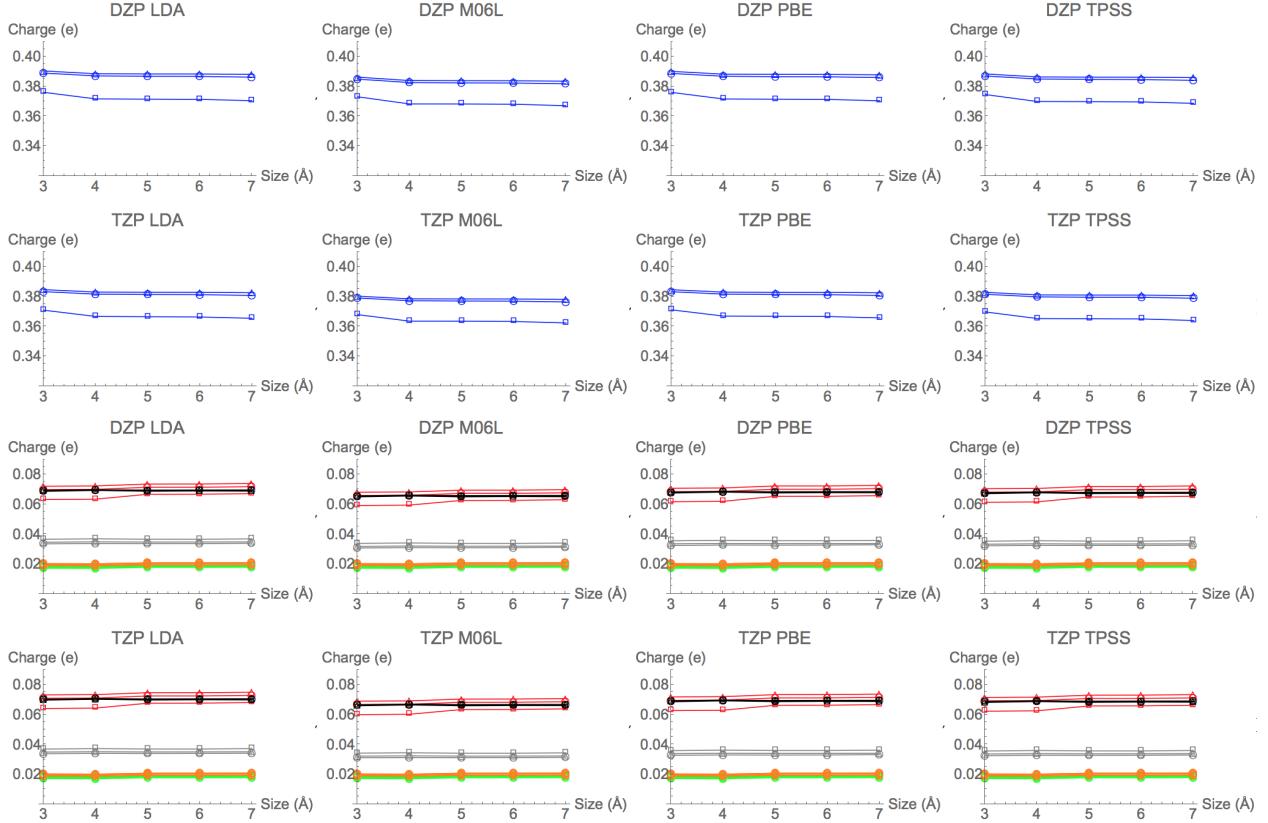

Figure S4: Charge density at critical points for C1–O1 (blue), C1–Ow (orange), Ring CP (green), Zn<sup>2+</sup>–O1 (grey), Zn<sup>2+</sup>–Ow (red), and Zn<sup>2+</sup>–N (black). Each plot shows results for one calculation method as active site model sizes increase in size from 3–7 Å. The three lines for each atom on each plot represent the three different starting QM/DMD configurations used with the following shapes: configuration 1-square, 2-circle, 3-triangle.

## Critical Point Motion

The motion of CPs is less dependent on functional or basis set choice than atomic charges and the values of  $\rho$  at CPs. The method of calculation has a smaller influence on the exact position of each CP than the nuclear configuration used or the size of model. The only

instance where the basis set has an impact on the trends of positions of CPs as system size increases is for 3–4 Å and 4–5 Å for the Zn–O1 bond CP movement using nuclear configuration 2 (Figure S6). The functional choice slightly changes the magnitude of distances moved in some cases, but does not change any trends in CP motion as system size changes.

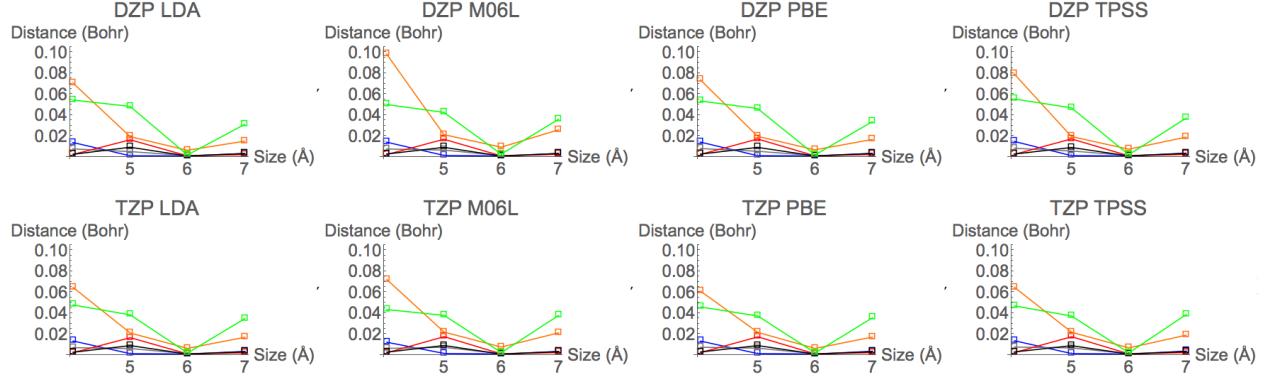

Figure S5: Movement of the CPs as the active site cluster model size increases for nuclear configuration 1 with all calculation methods using the following coloring: C1–O1 (blue), Zn<sup>2+</sup>–O1 (grey), Zn<sup>2+</sup>–Ow (red), Zn<sup>2+</sup>–N (black), C1–Ow (orange), and Ring CP (green).

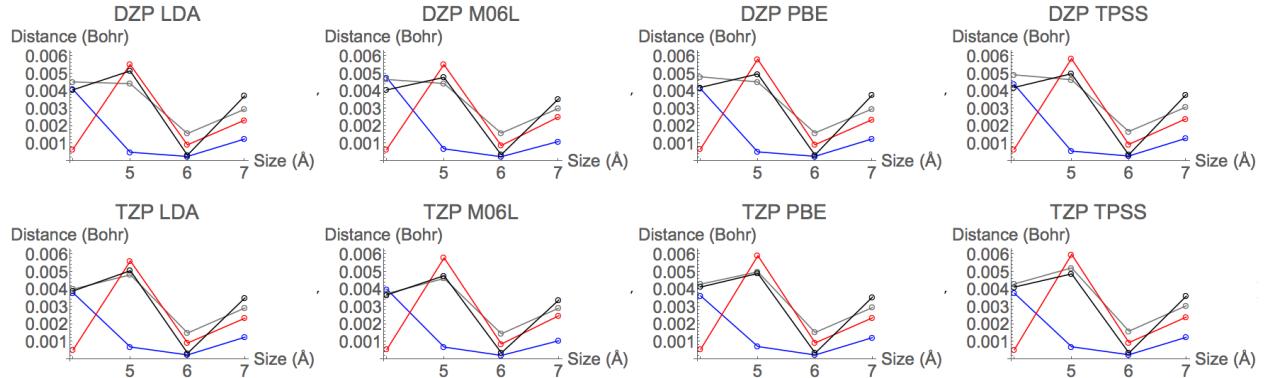

Figure S6: Movement of the CPs as the active site cluster model size increases for nuclear configuration 2 with all calculation methods using the following coloring: C1–O1 (blue), Zn<sup>2+</sup>–O1 (grey), Zn<sup>2+</sup>–Ow (red), and Zn<sup>2+</sup>–N (black).

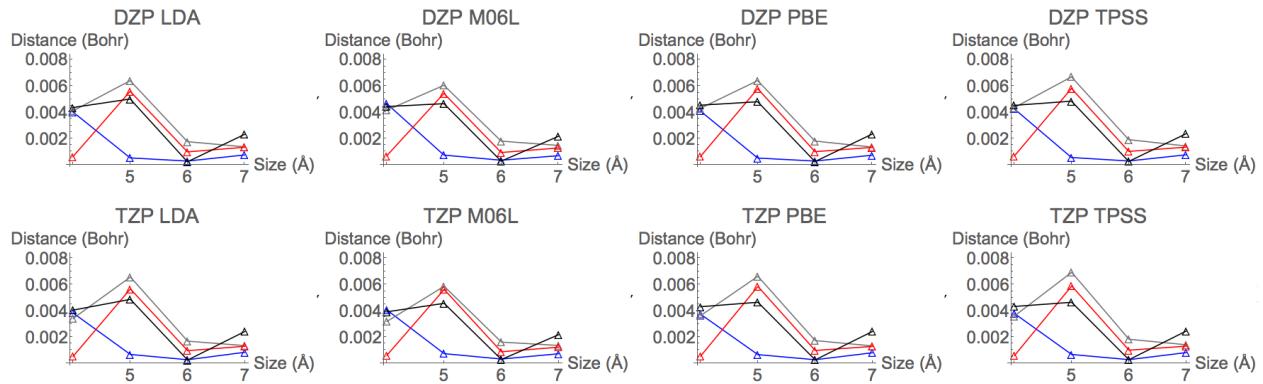

Figure S7: Movement of the CPs as the active site cluster model size increases for nuclear configuration 3 with all calculation methods using the following coloring: C1–O1 (blue), Zn<sup>2+</sup>–O1 (grey), Zn<sup>2+</sup>–Ow (red), and Zn<sup>2+</sup>–N (black).
