1. General Experimental Details

All reactions were performed using oven-dried glassware (200 °C) under an atmosphere of argon unless otherwise stated. Solvents were dried and distilled using standard methods. All boronic acids were purchased at the highest commercial quality from Sigma Aldrich, Alfa Aesar and Fluorochem. (Trimethylsilyl)diazomethane was obtained from Sigma Aldrich. All reagents were used without further purification.

Analytical thin layer chromatography (TLC) was performed using silica gel 60 F₂₅₄ pre-coated glass backed plates and visualized by ultraviolet radiation (254 nm) and/or Seebach reagent (12.5 g phosphomolybdic acid, 5.0 g cerium(IV)sulfate tetrahydrate, 16.0 mL water, 450.0 mL conc. sulfuric acid). Flash column chromatography was performed using high-purity grade silica gel (Merck grade 9385) with a pore size 60 Å and 230–400 mesh particle size under air pressure.

¹H NMR spectra were recorded on a 400 MHz DPX-400 Dual Spectrometer or a 600 MHz Avance 600 BBI Spectrometer as indicated. Chemical shifts are reported in ppm with the resonance resulting from incomplete deuteration of the solvent as the internal standard (CDCl₃: 7.26 ppm; (CD₃)₂SO: 2.50 ppm). ¹³C NMR spectra were recorded on a 600 MHz Avance 600 BBI Spectrometer with complete proton decoupling. Chemical shifts are reported in ppm with the solvent resonance as the internal standard (¹³CDCl₃: 77.16 ppm; (¹³CD₃)₂SO: 39.52 ppm). Data are reported as follows: chemical shift δ/ppm, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, qn = quintet, br = broad, m = multiplet or combinations thereof; ¹³C signals are singlets unless otherwise stated), coupling constants J in Hz, integration (¹H only). ¹H NMR signals are reported to 2 decimal places and ¹³C signals to 1 decimal place unless rounding would produce a value identical to another signal. In this case, an additional decimal place is reported for both signals concerned.

Infrared spectra were recorded neat as thin films or as solids on a Perkin-Elmer Spectrum One FTIR spectrometer and selected peaks are reported.

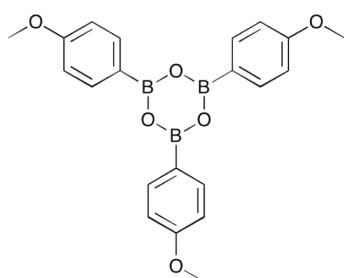

High resolution mass spectrometry (HRMS) was performed using positive electrospray ionisation (ESI+), on either a Waters Micromass LCT Premier spectrometer or performed by the Mass Spectrometry Service for the Chemistry Department at the University of Cambridge. All m/z values are reported to 4 decimal places and are within \pm 5 ppm of theoretical values.

Melting points were measured on a Stuart Scientific SMP3 melting point apparatus using a gradient of 0.5 $^{\circ}\text{C}.\text{min}^{-1}$.

2. Synthetic Procedure and Characterisation of Boroxines

General Procedure A for Preparation of Boroxines: A mixture of the boronic acid (0.5 g) in toluene (10 mL) was refluxed for 5-7 h with the use of a Dean-Stark trap. This boroxine was directly used in the next step without further purification.

6. Computational methods

Geometries of all structures (minima and saddle points) were optimised at the ωB97xd/cc-PVDZ level ωB97xD/cc-PVTZ//ωB97xD/cc-PVDZ level calculations using the implicit Solvation Model based on Density (SMD) implemented in Gaussian 09 software in dichloromethane as a solvent (using the SMD solvation model, $\epsilon=8.93$). Subsequent vibrational frequency calculations were performed at the same level for all calculated structures. When needed, multiple initial guesses (no more than four) were used to explore the conformational space fully. All transition states thus found possess exactly one negative Hessian eigenvalue, while all other stationary points were confirmed to be genuine minima on the potential energy surface (PES). Intrinsic reaction coordinate (IRC) analysis was performed to unambiguously assign located transition states when needed. Electronic energies were obtained by performing single-point calculations at the ωB97xd/cc-pVTZ level in solvent. Gibbs energies were calculated as $\Delta G = \Delta H - T\Delta S$ at 298 K where enthalpies and entropies were obtained by using standard statistical mechanical formulae for the ideal gas, rigid rotor, and harmonic oscillator approximations following the normal-mode analysis in vacuum. A correction of $(1.9 \cdot \Delta n)$ kcal mol⁻¹ (corresponding to the difference between the concentration of the ideal gas at 298 K and 1 atm and its 1 mol l⁻¹ concentration; Δn is the change in number of moles in the reaction) has been applied so that the computed values refer to 1 mol l⁻¹ standard state at a given temperature.

Cartesian coordinates and uncorrected electronic energies of all computed structures optimised at ωB97xd/cc-PVDZ + SMD level of theory.

For all the computed pathways, the following identification was used:

Start – the initial boronic species

TS1 – coordination transition state

Intermediate – tetra-coordinated boron intermediate

TS2 – migratory insertion transition state

Product – the final product of the migratory insertion

For the reaction pathways involving the same initial boronic species, the same coordinates were used.
