## Section S.1. Computational Details of Marcus Rate Parameters

## S.1.1 Reorganization Energy

The total reorganization energy $\lambda$ includes internal reorganization energy $\left(\lambda_{\text {int }}\right)$ and external reorganization energy $\left(\lambda_{\text {ext }}\right) .{ }^{1}$ The $\lambda_{\text {int }}$ derive from the changes in the ground-state structures of D and A when they gain or lose charge upon electron transfer, which is expressed as: ${ }^{2}$

$$
\begin{equation*}
\lambda_{\mathrm{int}}=\left[E\left(A^{-}\right)-E(A)\right]+\left[E(D)-E\left(D^{+}\right)\right] \tag{E.1}
\end{equation*}
$$

where $E\left(\mathrm{~A}^{-}\right)$and $E(\mathrm{~A})$ are the energies of the neutral acceptor A at the anionic and optimal ground-state geometries, respectively. $E\left(\mathrm{D}^{+}\right)$and $E(\mathrm{D})$ are the energies of the cation donor D at the neutral and optimal cation geometries, respectively.

However, the $\lambda_{\text {ext }}$ is due to electronic and nuclear polarization from the surrounding medium, which can be approximately evaluated by: ${ }^{3}$

$$
\begin{equation*}
\lambda_{e x t}=\frac{1}{4 \pi \varepsilon_{0}} \Delta e^{2}\left(\frac{1}{2 a_{1}}+\frac{1}{2 a_{2}}-\frac{1}{R}\right)\left(\frac{1}{\varepsilon_{\mathrm{OP}}}-\frac{1}{\varepsilon_{0}}\right) \tag{E.2}
\end{equation*}
$$

where $a_{1}, a_{2}, R, \varepsilon_{\mathrm{OP}}$, and $\varepsilon_{0}$ are donor radii, acceptor radii, the distance between the center of the donor and acceptor, and optical and the zero-frequency dielectric constants of the surrounding media, respectively. Considering the reconciliation between the computational cost and the accuracy, $\varepsilon_{\mathrm{OP}}$ and $\varepsilon_{0}$ is estimated to be 1.96 and 5 by Troisi ${ }^{4}$ and Jérôme ${ }^{1}$, respectively.

## S.1.2 Electronic Coupling

For the calculation of inter-CT and inter-CR rates, the electronic coupling can be approximated from the generalized Mulliken-Hush (GMH) formalism ${ }^{5,6}$ in adiabatic description, which could be written as below:
$V_{\mathrm{DA}}=\frac{\mu_{\mathrm{tr}} \Delta E}{\sqrt{(\Delta \mu)^{2}+4\left(\mu_{\mathrm{tr}}\right)^{2}}}$
where $\mu_{\mathrm{tr}}$ is the average transition dipole moment, $\Delta \mu$ is the dipole moment difference between initial state $S_{0}$ and final state $S_{\mathrm{n}}$, and $\Delta E$ corresponds to the vertical excitation energy. The $\Delta \mu$ can be estimated directly from a finite field method on the excitation energy. ${ }^{2}$

## S.1.3 Gibbs Free Energy

In the interface charge transfer processes, Gibbs free energy change of charge recombination $\left(\Delta G_{\text {inter-CR }}\right)$ can be expressed under the equation: ${ }^{7}$

$$
\begin{equation*}
\Delta G_{\mathrm{CR}}=E_{\mathrm{IP}}(\mathrm{D})-E_{\mathrm{EA}}(\mathrm{~A}) \tag{E.4}
\end{equation*}
$$

where $E_{\mathrm{IP}}(\mathrm{D})$ is the ionization potential of the donor which could be estimated by the HOMO energy of the donor, and $E_{\mathrm{EA}}(\mathrm{A})$ is the electron affinity of the acceptor which is considered to be the LUMO energy of the acceptor here. ${ }^{8}$

The Gibbs free energy change of exciton dissociation ( $\Delta G_{\text {inter-CS }}$ ), can be evaluated by the RehmWeller equation: ${ }^{7}$
$\Delta G_{\mathrm{CS}}=-\Delta G_{\mathrm{CR}}-\Delta E_{0-0}-E_{\mathrm{B}}$

Where $\Delta E_{0-0}$ is the lowest excited state energy of free-base donor and $E_{\mathrm{B}}$ is the exciton binding energy, defined as the energy difference between the electronic and optical band-gap energy. ${ }^{9}$

## Tables:

Table S1. Calculated and experimental bond lengths (in $\AA$ ), bond angles (in deg) and torsion angles (in deg) of the configuration $\mathbf{c}$ for 99'BF at $S_{0}$ state (B3LYP/6-31G(d)).
c

|  | Cal. | Exp. $^{\text {a }}$ |  | Cal. | Exp. $^{\mathrm{a}}$ |
| :--- | :---: | :---: | :--- | :---: | :---: |
