## Materials and Methods

### Materials and reagents

All reagents and solvents used were of commercially available reagent grade and were used without any additional purification.

### Characterization

<sup>1</sup>H NMR was carried out on a Bruker 400 spectrometer. Thermogravimetric (TG) analyses of the compounds were performed on a SDT 2960 thermal analyzer from room temperature to 400 °C at a heating rate of 10 °C/min under N<sub>2</sub> atmosphere. Elemental Analysis(EA) were carried out at on a FLASH EA 112 elemental analyzer.

### Powder X-ray diffraction (PXRD)

PXRD patterns of the compounds were collected at room temperature in air on a X'Pert PRO diffractometer (Cu-K $\alpha$ ). PXRD data for those with mother liquid were collected using Bruker D8 Advance diffractometer (Cu-K $\alpha$ ), during which the samples were packed and sealed in glass capillary with a small quantity of mother liquid.

### Single-crystal X-ray diffraction (SCXRD) measurements and details for structure determination

Single-crystal X-ray diffraction measurements of **Ag<sub>12</sub>TPPA·AA**, **Ag<sub>12</sub>TPPA·AB** and **Ag<sub>12</sub>TPPA·ABC\_250 K** were performed on a Rigaku XtaLAB Pro diffractometer with Cu-K $\alpha$  radiation ( $\lambda = 1.54178 \text{ \AA}$ ) at 250 K and **Ag<sub>12</sub>TPPA·ABC\_100 K** was measured with Mo-K $\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ) at 100 K. Data collection and reduction were performed using the program CrysAlisPro<sup>[1]</sup>. The intensities were corrected for absorption using empirical method implemented in SCALE3 ABSPACK scaling algorithm<sup>[2]</sup>. The structures were solved with intrinsic phasing methods (*SHELXT-2015*<sup>[3]</sup>) for **Ag<sub>12</sub>TPPA·AB**, direct methods (*SHELX*<sup>[4]</sup>) for **Ag<sub>12</sub>TPPA·AA** and **Ag<sub>12</sub>TPPA·ABC**, and refined by full-matrix least squares on F<sup>2</sup> using *OLEX2*,<sup>[5]</sup> which utilizes the *SHELXL-2015* module.<sup>[6]</sup> For each of the three structures, all hydrogen atoms were assigned isotropic displacement coefficients U(H) = 1.2U or 1.5U and their coordinates were allowed to ride on their respective atoms, and all non-hydrogen atoms, including the disordered fragments were located in difference-Fourier maps, and refined anisotropically. CF<sub>3</sub>COO<sup>-</sup>, -S<sup>t</sup>Bu and the silver atoms they coordinated all suffered positional disorder because of the lattice symmetry

with fixed occupancy.  $\text{CF}_3\text{COO}^-$  and  $-\text{S}^t\text{Bu}$  both located at the same position but can't co-exist. Therefore, the PART instruction was used to divide them into two groups. The F atoms of the  $\text{CF}_3\text{COO}^-$  are in two orientations located with equal occupancies. The benzene and pyridine rings of the TPPA molecules were also found to be disordered over two sites with the fixed occupancy of 0.5. The least-squares refinement of the structural model was performed under hard geometry restraints and displacement parameter restrains, such as SADI, ISOR, EADP and EXYZ for the  $\text{CF}_3\text{COO}^-$ ,  $-\text{S}^t\text{Bu}$  and TPPA molecule. In addition, modeling of electron density within the voids of the frameworks did not lead to identification of guest (DMAc) entities in structures, which is due to the seriously disorder arising from the quite weak interaction between guest and the host framework as well as the high lattice symmetry. Thus the remaining electron density was flattened out using the solvent masking protocol inside *OLEX2* which results in a decrease in the final R value. The information of the crystal data and refinement results for all compounds are summarized in Supplementary Table 1.

### Calculation of void space

The fraction of void space was calculated from X-ray structural data of **Ag<sub>12</sub>TPPA** by PLATON: The unit cell is filled with the atoms from the structural model and each specific atom is assigned its respective van der Waals radius. A grid search generates a list of grid points with a minimum distance of 1.2 Å from the nearest van der Waals surface. This list of grid points is then used to produce a new list of grid points that makes up the solvent accessible areas. For the sets of grid points, the center of gravity and volume of the void are calculated. The overall solvent accessible volume is calculated along with the volume and center of gravity of individual 'voids'.

### Luminescence decay measurements

Luminescence microscopy images were recorded on an Olympus BX 53 microscope, and measurements were carried out using a HORIBA FluoroLog-3 fluorescence spectrometer. Steady-state photoluminescence (PL) spectroscopy, emission decay spectroscopy and time-resolved emission spectroscopy (TRES) were performed on a HORIBA FluoroLog-3 spectrofluorometer equipped with an East Changing TC202 temperature controller; the spectra were recorded using the time-correlated single-photon counting (TCSPC) method. Before measurement of temperature-dependent steady and transient luminescence, **Ag<sub>12</sub>TPPA·AA** were first loaded into

the temperature-controlled instrument with each border of the sample cell sealed by vaseline in case of the solvent escaping and then evacuated for 30 min using a VALUE VRD-16 vacuum pump.

### SEM measurements

Scanning electron microscopy (SEM) measurement was carried out using ZeissSigma 500.

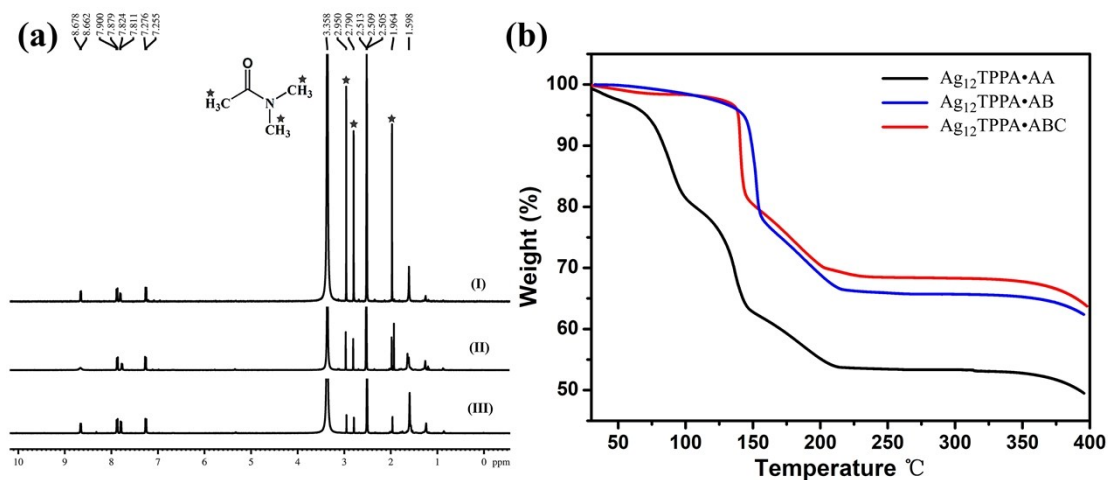

**Synthesis of  $\text{Ag}_{12}\text{TPPA}\cdot\text{AA}$ :**  $\text{AgS}^t\text{Bu}$  was prepared from the reaction of  $\text{Ag}_2\text{O}$  and  $\text{HS}^t\text{Bu}$  in  $\text{Et}_3\text{N}$ . The ligand TPPA was synthesized through Suzuki coupling of tris(4-iodophenyl)amine and pyridine-4-boronic acid according to a reported protocol.<sup>[7]</sup> In a typical reaction, addition of  $\text{CF}_3\text{COOAg}$  (0.045 g, 0.2 mmol) to a DMAc (dimethylacetamide) solution of  $\text{AgS}^t\text{Bu}$  (0.06 g, 0.3 mmol) under stirring gave a colorless clear solution, which was then heated to 40 °C followed by droplet addition of DMAc solution of TPPA (0.015 g, 0.3 mmol). Hexagon colorless crystals of  $\text{Ag}_{12}\text{TPPA}\cdot\text{AA}$  were obtained in minutes. (Yield: 94.8 % based on TPPA).

**Elemental Analysis:**  $\text{Ag}_{12}\text{TPPA}\cdot\text{AB}$  ( $\text{C}_{102}\text{H}_{102}\text{Ag}_{12}\text{F}_{18}\text{N}_8\text{O}_{12}\text{S}_6\cdot 1.7\text{DMAc}$ : calc.(%) C 36.21, N 3.76, H 3.27; found C 36.45, N 3.48, H 3.36).  $\text{Ag}_{12}\text{TPPA}\cdot\text{ABC}$  ( $\text{C}_{102}\text{H}_{102}\text{Ag}_{12}\text{F}_{18}\text{N}_8\text{O}_{12}\text{S}_6\cdot 0.9\text{DMAc}$ : calc.(%) C 35.83, N 3.52, H 3.13; found C 35.44, N 3.63, H 3.31).

**Figure S1.** The  $\text{C-H}\cdots\text{F}$  weak interactions between  $-\text{S}^t\text{Bu}$  and  $\text{CF}_3\text{COO}^-$  among adjacent layers (turquoise dash line) with the  $\text{H}\cdots\text{F}$  distances ( $\text{C-H}\cdots\text{F}$  angles) are 2.691 Å (154.6°) and 2.960 Å (153.7°), respectively. The  $\text{C-H}\cdots\text{O}$  weak interaction between  $^t\text{BuS}^-$  and  $\text{CF}_3\text{COO}^-$  among

adjacent layers (red dash line), the H $\cdots$ O distances (C–H $\cdots$ O angles) are 2.751 Å (170.2°), 2.847 Å (116.5°) and 3.060 Å (101.7°), respectively.

**Figure S2.** (a) <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 400 MHz) spectra of newly obtained **Ag<sub>12</sub>TPPA·AA** under different treatments: (I) rapidly dissolved in DMSO-*d*<sub>6</sub>; (II) exposed to air for 10 hours to allow the DMAC within the channel freely volatilize before dissolving in DMSO-*d*<sub>6</sub>; (III) stayed in mother liquid for 24 hours and then freely volatilize for 10 hours and dissolved in DMSO-*d*<sub>6</sub>. **Ag<sub>12</sub>TPPA·AA**, **Ag<sub>12</sub>TPPA·AB**, **Ag<sub>12</sub>TPPA·ABC** contain 8, 1.7 and 0.9 DMAC molecules corresponding to each Ag<sub>12</sub> cluster, respectively. (b) The TGA curves for **Ag<sub>12</sub>TPPA·AA**, **Ag<sub>12</sub>TPPA·AB**, **Ag<sub>12</sub>TPPA·ABC** under N<sub>2</sub> atmosphere (10 °C/min). **Ag<sub>12</sub>TPPA·AB** and **Ag<sub>12</sub>TPPA·ABC** display a 4% and 2% weight loss corresponding to about 1.7 and 0.9 DMAC molecules, respectively, up to 135 and 125 °C.
