Fox, Gaussian, Inc., Wallingford CT, 2013.

Website details

The structures are drawn in a molecular editor integrated in the website¹ – both the imine and nucleophile are entered in their active form. A list of recognized imines and nucleophiles can be found on page **S48** and a table of literature precedented combinations can found on page **S49**. As JMSE will always convert neighbouring opposite charges to a bond, triple bonds should be used to input diazo compounds. The application logic was coded in Python 2.7,² using RDKit for the chemoinformatic functionality.³ The result from the Python application is returned as text and images, which are integrated in a dynamic webpage and served by Apache webserver.⁴ The site is available at <http://www-mmm.ch.cam.ac.uk>. The full code can be found at github. <https://github.com/KristapsE/BINOPTimal>

Computational methods

Transition states were located first, by a conformational search in MacroModel (version 9.9)⁵ using the OPLS-2005 force field.⁶⁻⁸ Selected conformers within 10 kJ mol⁻¹ of the minimum were optimized using the ONIOM method implemented in Gaussian 09 (revision D.01).⁹ The B3LYP density functional,¹⁰⁻¹¹ and split-valence polarized 6-31G** basis set,¹²⁻¹³ were used for the high-layer, and the force field UFF,¹⁴ was used for the low-layer. The reactants and the phosphoric acid moiety of the catalyst were included in the high-layer, and the remaining regions of the catalyst

were treated as the low-layer. This method has previously been shown to give excellent results when used to describe reactions catalyzed by chiral phosphoric acids.¹⁵⁻²¹ The position of the partition within the catalyst was chosen as the phosphoric acid binds directly to the reagents, whereas the remaining catalyst acts as steric bulk and can be adequately described by molecular mechanics. Single point energy calculations were performed on the resulting structures using M06-2X density functional,²² and the 6-31G** basis set, as implemented in Gaussian 09 (revision D.01). This energy was used to correct the gas-phase energy derived from the ONIOM calculations. Free energies in solution were derived from structures optimized in the gas phase at the ONIOM (B3LYP/6-31G**):UFF), level of theory by means of a single point calculation using M06-2X/6-31G** with the polarizable continuum model (IEFPCM) as implemented in the Gaussian 09 (revision D.01), using *m*-xylene.²³ These values were used to correct the Gibbs free energy derived from the ONIOM calculations. To further validate the results key transition states from this process were re-optimized using the B3LYP functional and 6-31G* basis set. The free energies obtained from this process were corrected by a single point calculation in the same manner as above. Structures are illustrated using CYLview.²⁴

Transition state structures and methods comparison

The mechanism of this class of reactions is well established and computations of the full catalyst systems have led to the development of the model depicted below.²⁵ This is based on a projection of the catalyst such that both the BINOL oxygens are in the plane of the paper. The free oxygens are above and below, each having bulky substituents on either side. The catalyst binds to the substrate via the catalyst hydroxyl group and there is a second interaction from the phosphoryl oxygen to the nucleophile. The imine can orient itself with respect to the catalyst in one of two ways. Noting that the C_2 symmetry of the phosphate anion allows us to draw the imine at the front of the diagram without loss of generality, the *N*-substituent, can be directed away from the front 3,3' group, which we call *Type I*, or toward the 3,3' groups, which we call *Type II*. Additionally, the imine can exist as either the *E* or *Z* stereoisomer; we define *E* or *Z* based on steric size. Combining these considerations, four unique TSs, **TS1-4**, for these reactions are formulated.

Figure 1. Transition state models for the prediction of stereoselectivity.

TS2-Z: $\Delta\Delta G^\ddagger = +4.1$, $\Delta\Delta G_{\text{sol}}^\ddagger = +3.7$

TS1-Z: $\Delta\Delta G^\ddagger = +4.3$, $\Delta\Delta G_{\text{sol}}^\ddagger = +4.1$

TS1-E: $\Delta\Delta G^\ddagger = 0$, $\Delta\Delta G_{\text{sol}}^\ddagger = 0$

TS2-E: $\Delta\Delta G^\ddagger = +1.7$, $\Delta\Delta G_{\text{sol}}^\ddagger = +1.2$

Figure 2. Competing TS for the 3,5-CF₃C₆H₄ derived phosphoric acid catalysed phosphorylation of imines. ONIOM (B3LYP/6-31G^{**}:UFF), single-point energy M06-2X/6-31G^{**}. Grayed-out regions were treated with UFF, and the full-colour regions were treated B3LYP/6-31G^{**}. All energies in kcal mol⁻¹.

Figure 3. Competing TS for the TRIP derived phosphoric acid catalysed phosphorylation of imines. ONIOM (B3LYP/6-31G^{**}:UFF), single-point energy M06-2X/6-31G^{**}. Grayed-out regions were treated with UFF, and the full-colour regions were treated B3LYP/6-31G^{**}. All energies in kcal mol⁻¹.

In order to test the ONIOM method, we re-optimized **TS1-TS4** using the B3LYP functional and 6-31G* basis set and then carried out single-point energy evaluations using the M06-2X/6-31G** with the polarizable continuum model (IEFPCM) for *m*-xylene. The corrected free energies between the two methods are compared in Table 1. The qualitative patterns with both catalysts remain the same. Superposition of the pairs of transition states optimized by the different methods show the structural differences quantified through RMSD. These values are obtained from Maestro²⁶ and superimposed using the ASL feature. These calculations indicate the energy difference between **TS1-E** and **TS2-E** is overestimated by the ONIOM method (77% ee vs 50% ee). This could be due to the UFF component of the optimization, which overestimates short-range repulsion effects.^{17,27} Although the absolute values are larger as compared to our DFT optimized structures, both methods agree that TRIP should lead to higher levels of enantioselectivity.

| $\Delta\Delta G^\ddagger$ | ONIOM | | DFT | | RMSD |
|---------------------------|------------------------------------|--|------------------------------|--|--------|
| | M06-2X/6-31G**//B3LYP/6-31G** :UFF | $\Delta\Delta G^\ddagger_{\text{sol}}$ | M06-2X/6-31G**//B3LYP/6-31G* | $\Delta\Delta G^\ddagger_{\text{sol}}$ | |
| TS1-E | 0 | 0 | 0 | 0 | 0.3470 |
| TS1-Z | +4.3 | +4.1 | +6.8 | +6.5 | 0.4828 |

Summary of imines and nucleophile types recognized

Imine-nucleophile steric relationship table

A key decision in the tree is whether the *N*-substituent is small or large, but this generally depends on the nucleophile, so both reaction variables must be considered. For this purpose, we have analyzed a series of literature reactions for different combinations and developed general rules for when the *N*-substituent is small and when it can be considered large. Our level of confidence in assignment for a particular combination is tabulated. This can be either confident assignment (direct literature precedent), L or S, or probable assignment, PL or PS. The probable assignment is weighted on trends from similar combinations. For example, benzoyl is confidently determined to be large for reactions involving hydrogen peroxides, thiols and alcohols. It is therefore highly probable that it reacts comparably with similar nucleophiles (HCN, amines, imides etc.). In isolated cases the *N*-substituent size can be dictated by the size of the substituents at the carbon of the imine leading to a situation in which the combination can be both large, L and small, S. Although these reactions fit the decision tree they have been omitted from the BINOPTimal

database to avoid overly adapted rules for special cases. For these few isolated cases, BINOPTimal, indicates that it cannot make a prediction.

| Nucleophile | <i>N</i> -substituent | | | | | | | |
|------------------------|-----------------------|-----|-----|----------|--------|---------|----------|--------|
| | Acetyl | Boc | Cbz | Aromatic | Benzyl | Benzoyl | Sulfonyl | Cyclic |
| HCN | PL | PL | PL | PL | L | PL | PL | PS |
| hydrogen peroxides | PL | PL | PL | PL | PL | L | PL | PL |
| amines | PL | L | PL | PL | PL | PL | PL | PS |
| thiols | PL | PL | PL | PL | PL | L | PL | S |
| imides | PL | L | PL | PL | PL | PL | PL | PL |
| diazoesters | PL | L | PL | L | PL | PL | PL | PL |
| diazoamides | PL | L | PL | PL | PL | PL | PL | PL |
| diazophosphonates | PL | L | L | L | PL | PL | PL | PL |
| alcohols | PL | PL | PL | PL | PL | L | PL | PS |
| phosphonate | PL | PL | PL | L | PL | PL | PL | PL |
| Hantzsch esters | L | PL | PL | L | PL | PL | PL | L |
| benzothiazolines | PL | PL | PL | L | PL | PL | PL | PL |
| <i>N</i> -heterocycles | S | S/L | PL | PL | PL | PL | L | S/L |
| enols | S | S/L | PL | S | PL | PL | L | PS |
| acetylacetone | PL | L | PL | PL | PL | PL | PL | PL |
| enamines/enamides | S | S | PL | S | PL | PL | PL | PS |
| thiazolones | PS | PL | PL | PL | PL | L | L | PL |

Table 2. Imine-nucleophile steric relationship table. Nucleophile and imine (aldimine and ketimine) combination determine if the *N*-substituent can be considered L, large or S, small. Literature evidence does not exist for each combination. General rules have been developed based on theoretical studies and extensive literature surveys to determine if the combination would lead to a probably large, PL or small, PS, *N*-substituent.
