## I. THE VIBRATIONAL SELF-CONSISTENT FIELD (VSCF) THEORY

The vibrational self-consistent field theory[1-6] is one of the most used methodology to compute anharmonic vibrational spectra of polyatomic molecules. The VSCF invokes single particle approximation for the vibrational many-body problem. Here, the vibrational wave-function of a $N$ mode system is written as a product of $N$ one mode functions

$$
\begin{equation*}
\Phi_{q_{1}, q_{2}, \ldots, q_{N}}=\Pi_{i} \phi_{n_{i}}^{i}\left(q_{i}\right) . \tag{1}
\end{equation*}
$$

Each of such one mode function, usually refereed as modals, are expanded in an orthonormal basis functions (usually harmonic oscillator basis)

$$
\begin{equation*}
\phi_{n_{i}}^{i}=\sum_{m} \chi_{m}^{i} C_{m n} . \tag{2}
\end{equation*}
$$

The modals are then variationally optimized by minimizing the expectation values of vibrational Hamiltonian with respect to these basis functions. This leads to the working equations for the optimized modals

$$
\begin{equation*}
\left(h_{e f f}^{i}-\epsilon_{n}^{(i)}\right) \phi_{n_{i}}^{i}\left(q_{i}\right)=0 . \tag{3}
\end{equation*}
$$

Here $h_{\text {eff }}^{i}$ is the effective one-body Hamiltonian for the $i^{\text {th }}$ mode whose potential is generated by averaging the non-separable many-body Hamiltonian over other modes. The Eq. 3 are solved in self-consistent manner. Once the optimized modals are obtained, the VSCF energy of a particular vibrational state is obtained as the expectation value of the vibrational Hamiltonian with the optimized wavefunctions for that state.

## II. THE VIBRATIONAL COUPLED CLUSTER METHOD

There are two different representations possible to formulate the vibrational coupled cluster method. One is the basis set representation, formulated and used extensively by Christiansen and co-workers $[5,7,8]$. The second one is the bosonic representation developed and used by Prasad and co-workers[9-11]. We used bosonic representation in this study.

In the formulation of the VCCM in bosonic representation, first the effective harmonic oscillator (EHO) approximation $[6,9,10]$ is invoked to get optimized reference function for
the vibrational ground-state. In the EHO approximation, a product of $N$ Gaussian functions

$$
\begin{equation*}
\Phi_{0}=\exp \left(-\sum_{i} \omega_{i}\left(q_{i}-q_{i}^{0}\right)^{2} / 2\right) \tag{4}
\end{equation*}
$$

and is variationally optimized with respect to the $\omega_{i}$ and $q_{i}^{0}$ to obtain the vibrational groundstate wavefunction for a molecule with $N$ vibrational modes. The harmonic oscillator ladder operators are then defined with respect to this optimized $\Phi_{0}$

$$
\begin{align*}
a_{i} & =\sqrt{\frac{\omega_{i}}{2}}\left(q_{i}-q_{i}^{0}+\frac{1}{\omega_{i}} \frac{q}{d q_{i}}\right)  \tag{5}\\
a_{i}^{\dagger} & =\sqrt{\frac{\omega_{i}}{2}}\left(q_{i}-q_{i}^{0}-\frac{1}{\omega_{i}} \frac{q}{d q_{i}}\right) \tag{6}
\end{align*}
$$

We note that the optimized reference function $\Phi_{0}$ is the vacuum state for $a_{i}$.
Next, the VCCM wavefunction is parametrized with a double-exponential wave operator operating on the optimized vacuum state $\Phi_{0}$,

$$
\begin{equation*}
\left|\Psi_{g}\right\rangle=e^{-S} e^{\sigma}\left|\Phi_{0}\right\rangle . \tag{7}
\end{equation*}
$$

The cluster operators $S$ and $\sigma$ are expanded as

$$
\begin{align*}
S & =\sum_{i} s_{i} a_{i}^{\dagger}+\sum_{i \leq j} s_{i j} a_{i}^{\dagger} a_{j}^{\dagger}+\sum_{i \leq j \leq k} s_{i j k} a_{i}^{\dagger} a_{j}^{\dagger} a_{k}^{\dagger}+\ldots  \tag{8}\\
\sigma & =\sum_{i} \sigma_{i} a_{i}+\sum_{i \leq j} \sigma_{i j} a_{i} a_{j}+\sum_{i \leq j \leq k} \sigma_{i j k} a_{i} a_{j} a_{k}+\ldots \tag{9}
\end{align*}
$$

Next, the subsystem embedding condition[12] is used to decouple the equations for the $\sigma$ matrix elements from the equations for the $S$ matrix elements. The working equations for the cluster matrix element $S$, ground state energy $E_{g}$ and the cluster matrix elements $\sigma$ are given by

$$
\begin{align*}
\left\langle\Phi_{e}\right| H_{1}^{e f f}\left|\Phi_{0}\right\rangle & =0  \tag{10}\\
\left\langle\Phi_{0}\right| H_{1}^{e f f}\left|\Phi_{0}\right\rangle & =E_{g}  \tag{11}\\
\left\langle\Phi_{0}\right| H_{2}^{e f f}\left|\Phi_{e}\right\rangle & =0 \tag{12}
\end{align*}
$$

Here, $\Phi_{e}$ are the excited states, and $H_{1}^{\text {eff }}$ and $H_{2}^{\text {eff }}$ are the similarity transformed effective operators, defined as

$$
\begin{array}{r}
H_{1}^{e f f}=e^{-S} H e^{S} \\
H_{2}^{e f f}=e^{\sigma} e^{-S} H e^{S} e^{-\sigma} \tag{14}
\end{array}
$$

The effective Hamiltonians $H_{1}^{\text {eff }}$ and $H_{2}^{\text {eff }}$ are evaluated using the Baker-CampbellHausdorff expansion. We used a maximum of four-body expansion for both the cluster operator $S$ and $\sigma$ in Eqs. 8. Since the vibrational Hamiltonian with QPES has at-most four-body terms, the effective Hamiltonian $H_{1}^{e f f}$ and $H_{2}^{e f f}$ are also restricted to have up to four-body operators.

Finally, the coupled cluster linear response theory $[13,14]$ is used to calculate the vibrational excitation energies. In this approach, the effective Hamiltonian $H_{2}^{e f f}$ is diagonalized in the space of excited states of EHO. The excitation energies are obtained directly as the eigenvalues of $H_{2}^{\text {eff }}$. The configuration space for the $H_{2}^{\text {eff }}$ is defined by the excited state space with at most four quanta in all the modes.

## A. The second order vibrational perturbation theory

The second order vibrational perturbation theory (VPT2) is another popular method to calculate the anharmonic vibrational spectra of polyatomic molecules. Barone and co-workers[15-18] implemented a modified version of VPT2 method in Gaussian09. Here, the harmonic part of the Watson Hamiltonian is taken as zeroth-order Hamiltonian and the cubic and quartic terms are treated as perturbations. The working equation for the vibrational energy is given by

$$
\begin{equation*}
E(n)=\chi_{0}+\sum_{i} \omega_{i}\left(n_{i}+\frac{1}{2}\right)+\sum_{i \leq j} \chi_{i j}\left(n_{i}+\frac{1}{2}\right)\left(n_{j}+\frac{1}{2}\right) \tag{15}
\end{equation*}
$$

Here, $\omega_{i}$ are the harmonic frequencies, $n_{i}$ the vibrational states and $\chi_{0}$ and $\chi_{i j}$ are the zero point contribution and anharmonic constants. These parameters are derived from the cubic, quartic and Coriolis coupling terms of the PES[15]. The working equation for the vibrational fundamentals transitions is[15]

$$
\begin{equation*}
\nu_{i}=\omega_{i}+2 \chi_{i}+\sum_{i \leq j} \chi_{i j} \tag{16}
\end{equation*}
$$

It was shown that the computation of the anharmonic constants $\chi_{0}$ and $\chi_{i j}$ encounters singularities in the presence of strong vibrational resonances in the molecule. To overcome such singularity problem, a variational calculation is carried out with the states that are involved in the resonances $[15,18]$.
