[C <sub>1</sub> mpyr][N(CF <sub>3</sub> SO <sub>2</sub> ) <sub>2</sub> ]	1	0.0695	-0.4831	0.1088	-0.4236

Each room temperature experimental EPR spectrum had present the three peaks characteristic of the nitroxide. The first derivative spectra produced as an instrumental response was doubly integrated to give the area of the first, second, and third peak of the nitroxides spectrum. These peaks are designated as I-1, Io and I+1 respectively. The ratio of areas of  $I_0/I_{-1}$  as well as  $I_0/I_{+1}$  are reported along with their average and the 95% confidence intervals. For all experimental samples, serial dilutions from a stock of the radical were performed to ensure a consistent number of spins per unit volume. The EPR tubes used have small variations in their pathlength resulting in differences in the number of radicals present in the path of detection, however, the concentration of radical present remains consistent throughout the sample. We attribute increased signal to noise ratio in some samples to this diminished pathlength effect. In other words, some samples have less radicals in the path of detection and therefore a smaller signal which manifests the appearance of a higher signal to noise ratio. For a given solvent inclusion of a replicate with this feature does not correlate to increased error margins. Because each rotational diffusion coefficient was determined not from absolute intensities in comparison to other spectra but through an internal reference to the central peak and the concentration of radical was consistent among the samples the variation in pathlength had no observable effect on the calculated relative peak areas or the corresponding rotational diffusion coefficients. All replicates for a particular solvent show agreement within a 95% confidence interval.

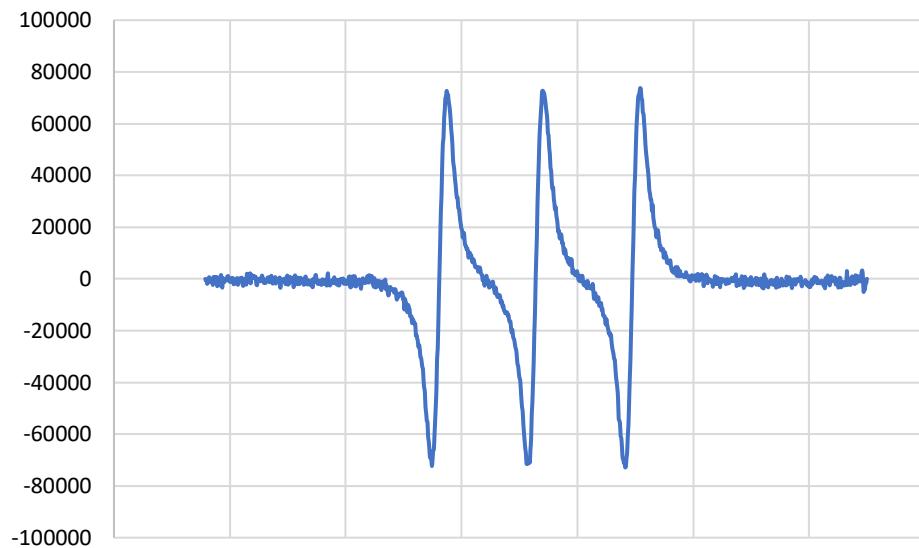

Table S6: Average areas of EPR peaks with potential error margins shown within a 95% confidence interval.
