5. Comparison between catalytic activity of Mn-MAMP and Mn-MAMP'

To understand the role of N–H functionality, we have substituted the N–H group by N–Me group to model **Mn-MAMP** and **Mn-MAMP'** complexes. The substituted methyl group can be directed towards the formate anion (**Mn-MAMP'**) or far from the formate anion (**Mn-MAMP**) as shown in Figure S3.

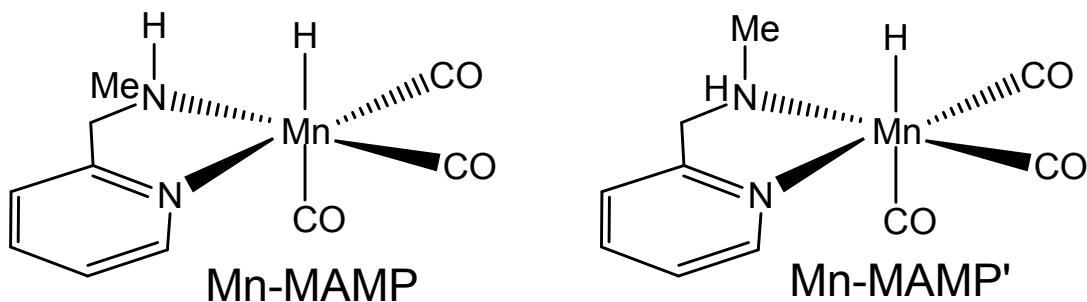

Figure S3: Structure of **Mn-MAMP** and **Mn-MAMP'** (Isomer of each other)

Our reaction free energy profile for CO₂ hydrogenation catalyzed by **Mn-MAMP** complex shows that hydride transfer is the rate determining steps (RDS), whereas hydrogenation by **Mn-MAMP'** shows that heterolytic H₂ cleavage is the RDS. Our calculated total reaction free energy barriers are same for **Mn-AMP** (21.3 kcal/mol) and **Mn-MAMP** (21.3 kcal/mol). This suggests that the presence of methyl group away from the formate anion does not affect the N–H···O hydrogen-bonding interactions between N–H and formate anion. On the other hand, **Mn-MAMP'** requires a total reaction free energy barrier of 25.4 kcal/mol, where Me-group is directed towards the formate anion. Therefore, the total reaction free energy barrier is 4.1 kcal/mol lower when catalyzed by **Mn-MAMP** complex over **Mn-MAMP'** complex. This shows the importance of

N–H functionality which forms N–H···O hydrogen-bonding interactions between N–H and formate anion when catalyzed via ligand assisted mechanism.

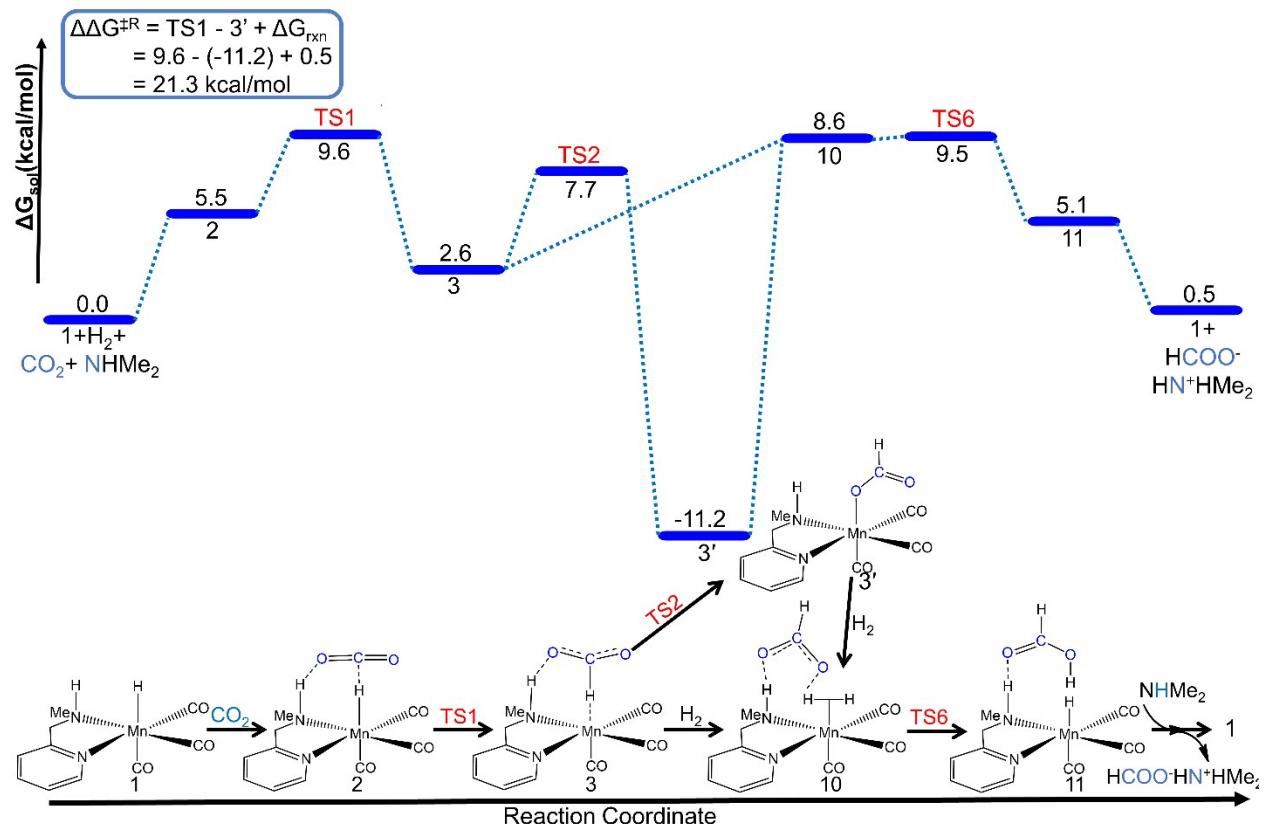

Figure S4: Reaction free energy profile diagram of CO_2 hydrogenation via ligand assisted mechanism catalyzed by **Mn-MAMP** complex. $\Delta\Delta G^{\ddagger R}$ and ΔG_{rxn} denote the total free energy barrier and total reaction free energy, respectively.

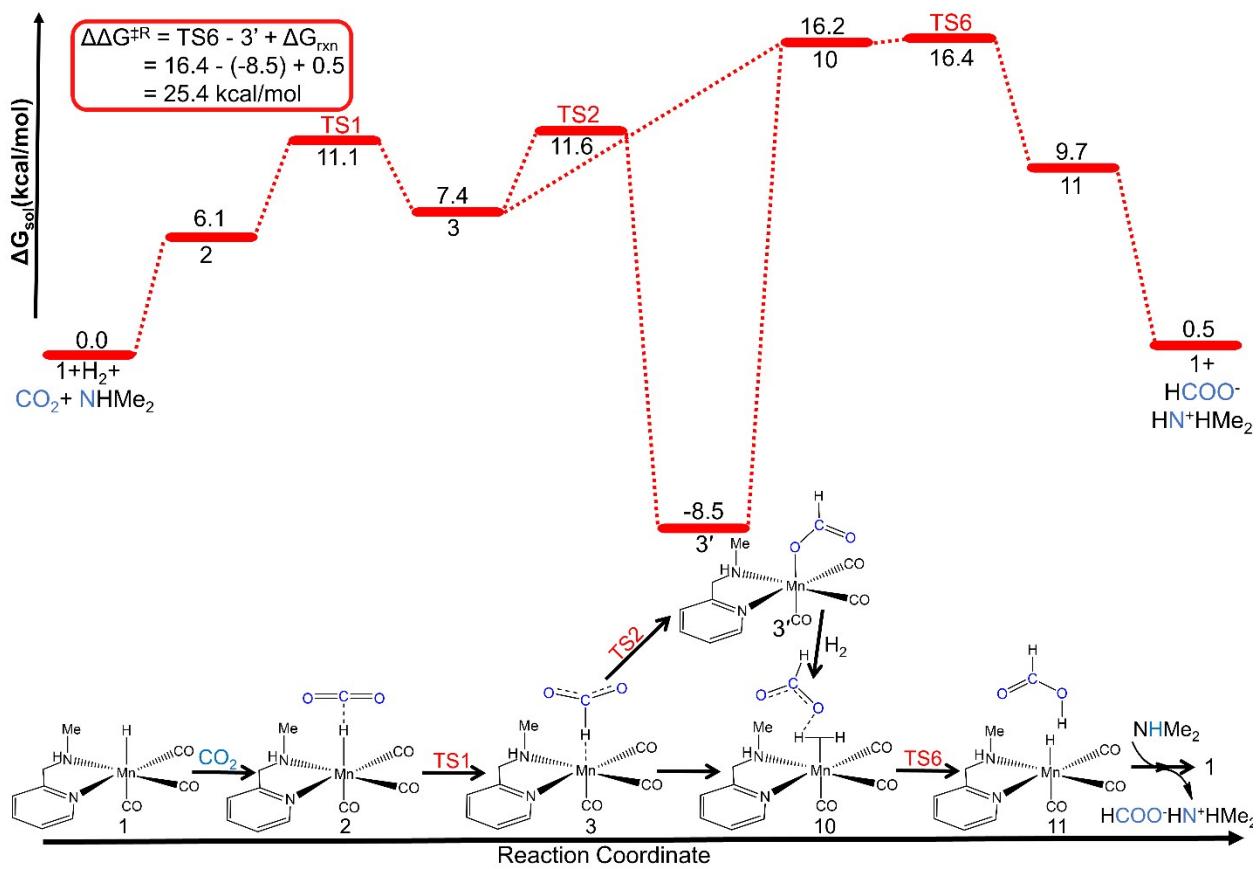

Figure S5: Reaction free energy profile diagram of CO_2 hydrogenation via ligand assisted mechanism catalyzed by **Mn-MAMP'** complex. $\Delta\Delta G^{\ddagger R}$ and ΔG_{rxn} denote the total free energy barrier and total reaction free energy, respectively.
