## Table of Contents

Table S1. Selected bond distances ( $\AA$ ) and angles $\left({ }^{\circ}\right)$ for compound 3.

|  |  | molecule B |
| :---: | :---: | :---: |
| Distances (Å) | molecule A |  |
| S1-C2 |  | $1.714(7)$ |
| C2-N2 | $1.710(6)$ | $1.297(9)$ |
| N2-N1 | $1.307(9)$ | $1.374(8)$ |
| N1-C1 | $1.355(8)$ | $1.305(8)$ |
| C1-S1 | $1.339(9)$ | $1.738(8)$ |
| C1-N4 | $1.735(8)$ | $1.348(9)$ |
| N4-C8 | $1.332(9)$ | $1.370(8)$ |
| C2-C3 | $1.420(9)$ | $1.443(10)$ |
| Angles (o) | $1.465(10)$ |  |
| C2-S1-C1 |  | $87.1(3)$ |
| C2-N2-N1 |  | $114.3(5)$ |
| N2-N1-C1 | $87.4(4)$ | $111.1(6)$ |
| N1-C1-S1 | $113.5(5)$ | $114.0(5)$ |
| C1-N4-C8 | $112.1(6)$ | $132.6(7)$ |
| N2-C2-S1 | $112.7(6)$ | $113.4(5)$ |

The observation of methanesulfenic acid or methanesulfenate anion is difficult under the conditions used, given its high reactivity. Instead, we sought to observe methanesulfonic acid (MW=96), as it is the most likely decomposition product of the sulfenic acid. It should be noted that $m / z=96$ is below the normal detection limit of the equipment ( $\mathrm{m} / \mathrm{z}=100$ ), but nevertheless, in the rare ESI-MS spectra recorded with data below $\mathrm{m} / \mathrm{z}$ of 100 , we detected a peak (negative mode at $\mathrm{m} / \mathrm{z}=95$, ca. $85 \%$, Fig. S25), which could be tentatively attributed to $\mathrm{CH}_{3} \mathrm{SO}_{3}{ }^{-}$.

Most of our ESI spectra are for $m / z>100$, so we also attempted to search for possible adducts with DMSO and/or MeOH in both positive and negative ESI-MS spectra. The only peaks to which some assignment can possibly be made is at ESI(-)-MS m/z=131 (( $\left.\mathrm{MeSO}_{3}{ }^{-} .2 \mathrm{H}_{2} \mathrm{O}\right)$, ca. $10 \%$, Fig S23) and $\mathrm{ESI}(+)-\mathrm{MS} \mathrm{m} / \mathrm{z}=178.8$, corresponding to $\left[\mathrm{H}\left(\mathrm{MeSO}_{3} \mathrm{H} .2 \mathrm{MeOH} . \mathrm{H}_{2} \mathrm{O}\right)\right]^{+}$(ca. $25 \%$, Fig. S24) in the positive mode. Given the low abundance and low mass of these peaks, along with the high noise of the ESI(-) spectrum, we refrained from making assignments to these signals in the main text.

Two independent molecules comprise the asymmetric unit of 3, S26 (a), and these adopt very similar conformations as seen in the overlay diagram in Fig. S26 (b). The five-membered ring is strictly planar (r.m.s. deviation $=0.002 \AA$ ) and this forms dihedral angles of $13.1(4)$ and $1.5(3)^{\circ}$ with the 4 fluorophenylamine and pyridyl substituents, respectively, reflecting a small twist about the N1-C8 bond as seen in the value of the C1-N1-C8-C9 torsion angle of $11.4(16)^{\circ}$; the dihedral angle between the outer substituents is $12.6(5)^{\circ}$. The second independent molecule is considerably more planar with the dihedral angles between the 1,3,4-thiadiazolyl ring and 4-fluorophenylamine and 2-pyridyl groups being 2.5(5) and $0.8(4)^{\circ}$. In each molecule, the pyridyl-N4 atom is orientated to be proximate to the ring-S1 atom with the S1 N N separation of 2.945 ( 8 ) Å (2.953(8) Å for the second molecule) suggestive of attractive contacts ${ }^{\text {Ref } S 1}$ consistent with the observed planar relationship between the 1,3,4-thiadiazolyl and pyridyl rings.

## Molecular packing

In the crystal of $\mathbf{2}$ supramolecular chains aligned along the $a$-axis and with a zigzag topology are formed through amine- $\mathrm{N}-\mathrm{H} \cdots$ (oxido) hydrogen bonding, Fig. S27 (a); details of the intermolecular interactions are given in the caption to Fig. S28. Chains are consolidated into the three dimensional architecture by a combination of pyridyl- $-\mathrm{C}-\mathrm{H} \cdots$ (oxido) (involving the other oxido- O atom) and $\mathrm{C}-\mathrm{H} \cdots$ (chelate) interactions as well as $\pi \cdots \pi$ stacking between pyridyl and fluorophenyl rings. Of particular interest is presence of the $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions as the $\pi$-system is defined by the $\mathrm{VSCN}_{2}$ chelate ring, Fig. S27 (b). Such $\mathrm{C}-\mathrm{H} \cdots \pi$ (chelate) synthons are gaining increasing recognition in the crystallographic literature, and in fact were probably first recognized in rings containing sulfur. ${ }^{R 1-R 4}$ Globally, the structure can be described in terms of columns of dimeric aggregates parallel to the $c$-axis connected by amine- N $\mathrm{H} \cdot \mathrm{O}$ (oxido) and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ (oxido) interactions; different views of the unit cell contents are shown in Figs. S27 (c) and S28.

Fig. S27. Molecular packing in 2: (a) view of the supramolecular zigzag chain mediated by $\mathrm{N}-\mathrm{H} . . \mathrm{O}$ hydrogen bonding and orientated along the $a$-axis, (b) dimeric aggregate sustained by methyl-C-H $\cdots \pi$ (chelate) and $\pi$ (pyridyl) $\cdots \pi$ (fluorophenyl)interactions, and (c) view in projection down the $c$-axis of the unit cell contents. The $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}, \mathrm{C}-\mathrm{H} \cdots \mathrm{O}, \mathrm{C}-\mathrm{H} \cdots \pi$, and $\pi \cdots \pi$ interactions are shown as orange, pink, blue, and purple dashed lines, respectively.

Fig. S28. Molecular packing diagram for 2: view of the unit cell contents in projection down the $a$-axis. Details of the supramolecular association: $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ (orange dashed lines) $\mathrm{N} 1-\mathrm{H} 1 \cdots \mathrm{O} 1^{i}=2.22(4) \mathrm{A}, \mathrm{N} 1 \ldots \mathrm{O} 1^{\mathrm{i}}$ $=2.959(4) \AA$ and, angle at $\mathrm{H} 1=142(3)^{\circ}$. C- $\mathrm{H} \cdots \mathrm{O}$ (pink dashed lines) C11-H11a $\cdots 2^{\mathrm{ii}}=2.47 \AA, \mathrm{C} 11 \cdots \mathrm{O} 2^{\mathrm{ii}}=$ $3.173(5) \AA$ and angle at $\mathrm{H} 11 \mathrm{a}=133^{\circ}$. C-H $\cdots \pi$ (blue dashed lines) $\mathrm{C} 9-\mathrm{H9b} \cdots\left(\mathrm{VSCN}_{2}\right)^{\mathrm{iii}}=2.77 \AA$, $\mathrm{C} 9 \cdots\left(\mathrm{VSCN}_{2}\right)^{\text {iii }}=3.647(5) \AA$ and angle at $\mathrm{H} 9 \mathrm{~b}=152^{\circ} . \pi \cdots \pi$ (purple dashed lines) $\mathrm{Cg}(\mathrm{C} 1-\mathrm{C} 6) \cdots \mathrm{Cg}(\mathrm{N} 4, \mathrm{C} 10-$ $C 14)^{\text {iii }}=3.514(7) \AA$ and angle of inclination $=4.0(5)^{\circ}$. Symmetry operations $-i:-1 / 2+x, 1 / 2-y,-1 / 2+z ; i i: 1 \frac{1}{2}-x$, $1 / 2+y, 1 ½-z ; ~ i i i: 1-x, 1-y, 1-z$.

The molecular packing of $\mathbf{3}$ features myriad of points of contact between the constituent molecules; geometric details are given in the caption to Fig. S26. The most prominent interactions are amine- N $\mathrm{H} \cdot \mathrm{N}($ thiadiazolyl) hydrogen bonds between the two molecules comprising the crystallographic asymmetric unit, leading to eight-membered $\{\cdots \mathrm{HNCN}\}_{2}$ supramolecular synthons; these are flanked by fluorophenyl-C-H"N(thiadiazolyl) interactions. The resultant dimeric aggregates are connected into a
linear supramolecular ribbon along the $c$-axis by pyridyl-C-H"F interactions as shown in Fig. S29 (a). Centrosymmetrically related ribbons are connected into double ribbons by $\pi \cdots \pi$ stacking interactions between S1-thiadiazolyl rings, and between N4-pyridyl and S2-thiadiazolyl rings, as well as $\mathrm{F} \pi \pi$ (fluorophenyl) interactions, Fig. S29 (b). The double ribbons are connected into a three dimensional architecture via pyridyl-C-N $\cdots$ (fluorophenyl) interactions, Fig. S29 (b).

Fig. S29. Molecular packing in 3: (a) view of the supramolecular ribbon along the $c$-axis, and (b) view in projection down the $a$-axis of the unit cell contents. The $N-H \cdots N, C-H \cdots N, C-H \cdots F, \pi \cdots \pi, C-F \cdots \pi$ and C-H $\cdots \pi$ interactions are shown as blue, green, orange, pink, purple, and brown dashed lines, respectively.
