

## Supplementary Information

### Appendix 1. FLG synthesis details

Crucibles containing the expandable graphite were placed for 4 min pre-heated and in a furnace maintained at 900°C under air flow after what, they were retrieved and allowed to cool down to room temperature. A dispersion of the 52 wt.% of resulting expanded graphite was performed by two successive mechanical exfoliations in 2.2 L of propan-2-ol to reach a 3 g.L<sup>-1</sup> nominal concentration. The first one consisted in a homogenization with a shear mixer (Silverson L5M) for 15 min at 8000 rpm for each batch. During the second one, a probe sonication at 50% amplitude for 90 min (Vibra cell 75042, 13mm-diameter probe, 500 W, 20 kHz) was carried out by batches of 200 mL. The collected material was diluted to reach a nominal concentration of 0.2 g.L<sup>-1</sup>.

Selection of FLG by removal of too thick (> 100 nm) particles and agglomerates was performed by centrifugation at 2000 rpm for 1h (Thermofisher scientific Heraeus Megafuge 40, rotation acceleration = 9, rotation deceleration = 3). Because, after storage, particles may agglomerate at the bottom of the containers, a brief sonication of 10 min in the same conditions as described above was carried out immediately prior to centrifugation. The residue was discarded. Once the supernatant collected, a filtration on a cellulose nitrate membrane (45 mm diameter, 0.45 µm pore size) was performed followed by washing the particles with deionised water (1 volume of deionised water per volume of suspension).

**Table S1.** Identification and description of DEGs involved in *N. palea* exposed to *FLG*<sub>50mg</sub>

## Appendix 2. Discussion of the relation between a transcription factor nuclear-encoded with the regulation of chlorophyll pigment biosynthesis pathway.

A part of the plastid genome encodes for proteins involved in photosynthesis<sup>84</sup>. Among all plants, chlorophyll biosynthesis pathway starts in the cytoplasm with the chloroplast glutamate tRNA, which after several enzymatic reactions forms the 5-aminolevulinic acid synthesis<sup>85</sup>. This plastid encoded factor was found down-regulated in diatoms exposed to high FLG concentration (TG01\_diatome\_CL533Contig1\_2; Log2FC = -1.22). In our dataset, almost all protein complexes and enzymes involved in the chlorophyll biosynthetic pathway were down-regulated in diatoms exposed to high FLG concentration. Genes encoding for these proteins might be grouped and submitted to the same regulation process such as Rho termination factor previously discussed, found up-regulated in this condition. Genomic analysis undertaken by Yu and co-workers (2014)<sup>86</sup> suggested that environmental stress, such as light, can induce the formation of functional modules by nuclear-encoded transcription factors which can mediate the regulation of plastid gene expression. This could be the case here, where Rho termination factor might be nuclear-encoded and act on chloroplast gene expression. Thus, we can hypothesize that the up-regulation of the transcript homologous with a Rho termination factor could be linked with the down-regulation of all DEGs encoding for enzymes involved in chlorophyll biosynthetic pathway.
