**Table 1S** Reference values<sup>\*</sup> employed for  $\alpha_M$  calculation. See text for details.

\* For iron(III) hydrolysis, the selected values were found from Leslie Pettit and Gwyneth Pettit, SC-Database, Academic Software, extrapolating the most reliable literature values at I = 0. EDTA protonation and complexation constants are from Arthur E. Martell, Robert M. Smith - 1989 - Stability Constants, Chemical Society (London)

## Complexation and protonation constant of the monomeric unit in solution

## Experimental

Complex formation equilibria of AHP with Fe(III) were revisited[1S] since the published results were partial. Titrations were done in a thermostated glass cell, equipped with a magnetic stirrer, a DL 53 titrator, Mettler Toledo, with a combined DG 115-SC. Fe(III) complex formation constants were determined potentiometrically. Solutions were titrated with 0.1 M KOH at 25.0 °C, and 0.1 M KNO<sub>3</sub> ionic strength. The electrode was daily calibrated for hydrogen ion concentration by titrating HNO<sub>3</sub> with KOH in the above experimental conditions and the results were analysed with Gran procedure. [2S] The complex formation constants were studied using constant ligand concentration and 1:1, 1:2 and 1:3 metal/ligand molar ratios. Potentiometric data were processed with Hyperquad [3S] program. The reported log  $\beta$  values are referred to the overall equilibria:  $mM + pH + nL \rightleftharpoons MH_pL_n$  (the charges are omitted), where *m* might also be 0, in the case of protonation equilibria, and *p* can be negative.
