SI2. NMR experiments

In a typical experiment, 10 mg of solid were dissolved in 0.6 mL of deuterated dimethylsulfoxide (DMSO-d_6). The resulting orange solutions were directly used for NMR data collection. Due to all protons of GND^+ and $AmGND^+$ are susceptible to hydrogen–deuterium exchange, the progress of the reaction was monitored by gradual decrease of DMA^+ signal in ^1H NMR (2.58 ppm). The presence of GND^+ and $AmGND^+$ was demonstrated by the signal of imine group in ^{13}C NMR (158.5 ppm for GND^+ and 159.6 ppm for $AmGND^+$).

Thermogravimetric analysis

Compound **1** is thermally stable up to 200 °C where it shows a first weight loss of 20.4% close to 240 °C, that agrees well with the loss of the two molecules of dimethyl amine molecules (Calc: 20.1%). This is followed by the gradual decomposition of the framework that extends from 300 until ca. 600 °C. Thermal stability is similar to previously reported charge-assisted cation/anion hydrogen-bonded frameworks (decomposition between 240 and 300 °C).[2] In contrast, the compound **1** after being replaced with GND^+ or $AmGND^+$ shows two distinctive weight losses before decomposition at 400 °C that are ascribed to the departure of DMA and GND or AmGND molecules, respectively.

TG analysis of **1** after exposure to water shows a first weight loss of about 23% that corresponds to the loss of 12 molecules of water.
