## JOB's Plot

This method is based on the measurementof a series of solutions in which molar concentrations of two reactants varybut their sum remains constant. The fluorescence intensity of each solution was measuredat a suitable wavelength and plotted against the mole fraction of one reactant. Amaximum in fluorescence intensity appeared at themole ratio corresponding to the combiningratio of the reactants.The composition of the complex was determined by JOB's method and found to be (1:1) with respect to ligand for Hg<sup>2+</sup>.

Fig. S12. JOB's plot for Hg<sup>2+</sup>.

## **Calculation of LOD value**

To determine the detection limit, fluorescence titration of  $H_2L^3$  with  $Hg^{2+}$  was carried out by adding aliquots of micromolar concentration of  $Hg^{2+}$ .

However, the detection limit (LOD) of  $Hg^{2+}$  have been calculated by  $3\sigma$  method.

$$LOD = 3 \times S_d/S$$

where  $S_d$  is the standard deviation of the intercept of the blank ( $H_2L^3$ ) obtained from a plot of FI vs.

 $[H_2L^3]$ , and S is the slope obtained from linear part of the plot of FI vs. $[Hg^{2+}]$ .

Fig.S13. LOD of Hg<sup>2+</sup>

## **Calculation of Quantum Yield:**

Fluorescence quantum yields ( $\Phi$ ) were estimated by integrating the area under the fluorescence

curves using the equation,

$$\Phi_{sample} = (OD_{std} \times A_{sample})/(OD_{sample} \times A_{std}) \times \Phi_{std}$$

Where  $A_{sample}$  and  $A_{std}$  are the area under the fluorescence spectral curves and  $OD_{sample}$  and  $OD_{std}$  are the

optical densities of the sample and standard, respectively at the excitation wavelength.

Fluorescein has been used as the standard with  $\Phi_{std} = 0.5$  in ethanol for measuring the quantum yields of  $H_2L^3$  and of  $[Hg(HL^3)]^+$  Complex.
