Comparison of different computational methods

Method A denotes our default method in which geometry optimization and energy calculation were performed by using B3LYP-D3(BJ) method,¹ Def2-SVP basis set,² SMD solvation model³ associated with the addition of 2.6 kcal/mol for entropy correction⁴ and 1.9 kcal/mol for standard state change from 1 atm. to 1 mol/L at 298.15 K.⁵ Method B is different to method A in two aspects. First, the solution-phase E(0) were calculated by using B3LYP-D3(BJ) method, Def2-TZVP basis set,² SMD solvation model based on the structures optimized with method A. Second, method B corrected entropy effect by using the Morokuma's strategy that only considers vibrational and rotational entropy terms.⁶ The relative Gibbs free energies of the key transition states and intermediates were calculated by the two methods for comparison (Table S1) and detailed results were listed in Table S2 and Table S3. As shown in Table S1, the two methods both predict that the amide bond formation from **1** and **2** proceeds via the nucleophilic addition of dithiocarbamic acid on thiocarboxylic acid, and the rate-determining dithiocarbamic-acid-assisted 1,3-acyl transfer.

IRC analysis were performed by using G09 program with 10 points along the reverse and forward reaction paths to examine, respectively. Thereafter, the 1st and 21st points obtained in IRC analysis were further optimized as minima and they can transform into the corresponding intermediates. The IRC plots and the structures of the related 1st and 21st points were shown in Figure S4.
