**Section S1**: Tanabe’s hypothesis

![Diagram](image)

(a) charge difference = \((+4/6-2/2) \times 6 = -2\)

(b) charge difference = \((+4/4-2/3) \times 4 = +4/3\)

**Fig. S1.** Model structures of TiO\(_2\)–SiO\(_2\) and SiO\(_2\)–TiO\(_2\) pictured according to Tanabe’s hypothesis.

(a) with SiO\(_2\) as the major oxide; (b) with TiO\(_2\) as the major oxide.

The SiO\(_2\) is major component oxide in the structure of TiO\(_2\)-SiO\(_2\), which is shown in Figure S1 (a). According to Tanabe’s hypothesis the charge difference for each bond is \((+4/6-2/2) = -1/3\), and for all the bonds the valence unit is \((+4/6-2/2) \times 6 = -2\). In this case, the Brønsted acidity is assumed to appear in the presence of an excess of the negative charge, because three protons are considered to be associated with six oxygens to keep the electric neutrality. Although the TiO\(_2\)-SiO\(_2\) adsorbent exhibits big specific surface area and showed good performance, the TiO\(_2\)-SiO\(_2\) binary oxide itself exhibits the Brønsted acidity or Lewis base which is not benificial for adsorbing sulfur at low temperatures. However, if the binary oxide mode was changed into TiO\(_2\)-SiO\(_2\) with TiO\(_2\) being the major component, the result will be contrary for
effect. The structure of TiO$_2$-SiO$_2$ with TiO$_2$ being the major component oxide is shown in Figure S1 (b). According to Tanabe’s hypothesis, the charge difference for each bond is $(+4/4-2/3)=+1/3$, and for all the bonds the valence unit of $(+4/4-2/3)*4=+4/3$ is excess. In this case, the Lewis acidity is assumed to appear in the presence of an excess of the positive charge. Thereby the adsorption capacity of thiophene sulfurs and their derivatives would be significantly enhanced at low temperatures owing to high specific surface and rich Lewis acidity of the mesoporous TiO$_2$-SiO$_2$ binary oxide.

**Section S2:** The effect of preparation method on desulfurization performance

Figure S2 give a clear comparison of the desulfurization efficiencies of Ti-Si-40 adsorbent by different preparation methods in the same conditions. As is can be seen, the titania and silica powder adsorbent cannot meet the deep desulphurization requirement by simple extrusion, confirmed that TiO$_2$-SiO$_2$ complex oxides can generated adsorption sites by sol-gel.
