## 1. IR and XPS of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A

Before the measure of *SF* of the adsorbent towards ReO<sub>4</sub><sup>-</sup> against NO<sub>3</sub><sup>-</sup>, the anion of the gel should be exchanged into NO<sub>3</sub><sup>-</sup> in order to get rid of the effect of Br<sup>-</sup>. PC<sub>2</sub>-C<sub>12</sub>vimBr-A was immersed into excess *ca.* 1.5 M HNO<sub>3</sub> to equilibrium for 2 times, then into water for 3 times and dried. To confirm the exchange was complete and the polycation of the gel had no change in the ion-exchange process, IR and XPS were performed to the resulted PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A (Fig. S1).

Fig. S1 (a.) IR and (b.) XPS of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A prepared from PC<sub>2</sub>-C<sub>12</sub>vimBr-A.

The absorption peak at 1327 and 829 cm<sup>-1</sup> of NO<sub>3</sub><sup>-</sup> occurred in the IR spectrum of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A, while the other part of the spectrum was similar to that of PC<sub>2</sub>-C<sub>12</sub>vimBr-A, indicating that NO<sub>3</sub><sup>-</sup> had been exchanged onto the gel and the polycation showed no change. In the XPS of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A, the peak of Br disappeared, and the peak of N was divided into double peaks, which belonged to the N atoms in NO<sub>3</sub><sup>-</sup> and imidazolium respectively.

2. IR spectra of C<sub>2</sub>vimBr, C<sub>12</sub>vimBr, C<sub>6</sub>vim<sub>2</sub>Br<sub>2</sub>, PC<sub>2</sub>vimBr, PC<sub>2</sub>-C<sub>12</sub>vimBr-A and PC<sub>12</sub>vimBr.

Fig. S2 IR spectra of C<sub>2</sub>vimBr, C<sub>12</sub>vimBr, C<sub>6</sub>vim<sub>2</sub>Br<sub>2</sub>, PC<sub>2</sub>vimBr, PC<sub>2</sub>-C<sub>12</sub>vimBr-A and PC<sub>12</sub>vimBr.

IR was performed to the monomers, crosslinker and the resulted gels (Fig. S2). The IR spectra of C<sub>2</sub>vimBr, C<sub>6</sub>vim<sub>2</sub>Br<sub>2</sub> and PC<sub>2</sub>vimBr were similar to those we reported before<sup>1</sup>. The IR spectrum of C<sub>12</sub>vimBr was similar to that of C<sub>2</sub>vimBr, but the peak of the alkyl chain at 2916 and 2850 cm<sup>-1</sup> were much stronger. The IR spectra of PC<sub>2</sub>-C<sub>12</sub>vimBr-A and PC<sub>12</sub>vimBr were similar to those of the monomers and the crosslinker, but the peaks of vinyl around 1649-1660 cm<sup>-1</sup> and in 900-1000 cm<sup>-1</sup> disappeared in the resultant gels, indicating the successful synthesis of gels.

### 3. TGA of PC<sub>2</sub>vimBr, PC<sub>2</sub>vimNO<sub>3</sub>, PC<sub>2</sub>-C<sub>12</sub>vimBr-A and PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A

Fig. S3 TGA of (a) PC<sub>2</sub>vimBr, (b) PC<sub>2</sub>vimNO<sub>3</sub>, (c) PC<sub>2</sub>-C<sub>12</sub>vimBr-A and (d) PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A.

TGA was performed for different gels (Fig. S3). The gels with Br<sup>-</sup> anion had good thermal stability under 250°C, while those with NO<sub>3</sub><sup>-</sup> began to decompose at lower temperature of *ca.* 220°C. Since all gels were stable under 200°C and a flat curve were obtained at that temperature, the gels at 200°C was considered as dried completely, and the  $w/w_0$  at those points was marked in the figures.

### 4. EA of PC<sub>2</sub>-C<sub>12</sub>vimBr gels

Table S1 EA of PC<sub>2</sub>-C<sub>12</sub>vimBr gels

Sample	N (wt%)	C (wt%)	H (wt%)
PC <sub>12</sub> vimBr	7.78	57.1	9.12
PC <sub>2</sub> -C <sub>12</sub> vimBr-A	8.40	55.4	8.66
PC <sub>2</sub> -C <sub>12</sub> vimBr-B	9.31	51.2	8.14
PC <sub>2</sub> -C <sub>12</sub> vimBr-C	10.1	47.8	7.52
PC <sub>2</sub> -C <sub>12</sub> vimBr-D	11.3	43.5	6.74

N contents of PC<sub>2</sub>-C<sub>12</sub>vimBr gels increased from PC<sub>12</sub>vimBr to PC<sub>2</sub>-C<sub>12</sub>vimBr-D, corresponding to the increasing ratio between C<sub>2</sub>vimBr units and C<sub>12</sub>vimBr units, while the C and H content decreased.

## 5. XPS of PC<sub>2</sub>-C<sub>12</sub>vimBr gels

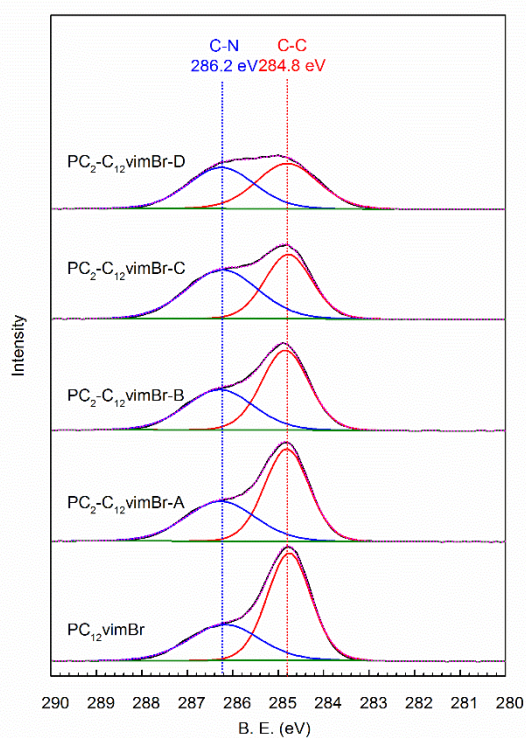

Fig. S4 XPS of PC<sub>2</sub>-C<sub>12</sub>vimBr gels

The XPS of C element in PC<sub>2</sub>-C<sub>12</sub>vimBr gels were shown in Fig. S4. The C 1s peaks in the XPS showed that the C in the gels could be divided into 2 kinds, namely C (C-N) and C (C-C). The C (C-N) atoms have higher B. E. than those of the C (C-C) atoms on the alkyl chains<sup>2</sup>. As the C<sub>2</sub>vimBr content increased from 0 in PC<sub>12</sub>vimBr to 80 mol% in PC<sub>2</sub>-C<sub>12</sub>vimBr-D, the relative intensity of C-C peak vs. C-N peak decreased. It agreed with their composition of the gels, because C<sub>12</sub>vimBr units had more C (C-C) atoms in the alkyl chains.

## 6. SF of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub> gels

Fig. S5 SF of PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub> gels

The  $c_0$  was 700 ppm and HNO<sub>3</sub> was 0.0500 mol kg<sup>-1</sup>. Phase ratio was 1 mg gel / 1 g solution.

PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub> gels were exchanged into PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub> gels by HNO<sub>3</sub>, then the  $SF$  were measured in a similar way as described in the paper. The  $q$  and  $SF$  decreased as the content of the hydrophobic units decreased, from PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-A to PC<sub>2</sub>-C<sub>12</sub>vimNO<sub>3</sub>-D. Though the hydrophilic cation unit, C<sub>2</sub>vim<sup>+</sup>, has smaller molecular weight, the  $q$  still decreased as its content increased. So it was illustrated that the hydrophobic cation unit, C<sub>12</sub>vim<sup>+</sup>, would bring a higher adsorption selectivity towards ReO<sub>4</sub><sup>-</sup> against NO<sub>3</sub><sup>-</sup>.
