2. Procedures for the synthesis of homoallylic alcohols^[1]

2.1 General Procedure

Under Ar, triphenylphosphine (2.62 g, 10 mmols, 1 equiv) was dissolved in dry toluene (9 mL). To this was added 3-bromopropan-1-ol (0.9 mL, 10 mmol, 1 equiv) and refluxed for 4 h. After this time, the reaction was allowed to cool, solids filtered, washed with cold diethyl ether and dried under vacuum to afford 3-(triphenylphosphonium)propan-1-ol-bromide as a white powder (4.0 g, 80%) which was used without purification in the next step.

Lithium bis(trimethylsilyl)amide (1 M in THF, 2.8 mL, 3.5 equiv) was added dropwise to 3-(triphenylphosphonium)propan-1-ol-bromide (400 mg, 1 mmol, 1.25 equiv) in THF (5 mL) under N_2 at -20°C . This was allowed to stir for 30 min before addition of the desired aldehyde (0.8 mmol, 1 equiv). This solution was then stirred overnight and allowed to warm to room temperature. The reaction was quenched by addition of aqueous NH_4Cl . 1 M HCl was added to take the solution to pH 1, extracted with CH_2Cl_2 , dried over Na_2SO_4 and concentrated under reduced pressure. The resultant oil was purified by flash column chromatography (10% EtOAc/ CH_2Cl_2) to yield product.

(Z)-4-(*p*-Tolyl)but-3-en-1-ol^[3] [(Z)-2c]

Commentary on synthesis: To synthesize the *Z* homoallylic we opted to conduct an unselective Wittig reaction. Surprisingly, no reaction was observed when employing the unprotected phosphonium bromide under typical unselective Wittig conditions (NaH, KO^tBu, NaHMDS). As such we hypothesised that the prior Wittig was in part successful due to the lithium coordination with the free alcohol. We therefore protected the alcohol which allowed us to access a mixture of *Z/E* alkenes. While the protection was facile, formation of the phosphonium was significantly slower (24 h, reflux, approx. 70% conversion by ³¹P NMR). Further to this, the phosphonium was now a dense oil, unsuitable for purification by filtration. Instead, the toluene was decanted off before addition of THF and addition of NaHMDS in THF (1 M). This reaction was quenched by addition of NH₄Cl (sat. soln.) and the organic extracted with diethyl ether. The organic phase was dried over MgSO₄ and concentrated. This was then subjected to TBAF in THF (1M) which in turn was concentrated and purified over silica gel eluting 10% EtOAc/CH₂Cl₂ to yield a 2.7:1 mixture of *Z* and *E* isomers:

3-Bromopropan-1-ol (0.2 mL, 2.1 mmol, 1 equiv) was allowed to stir in dry CH_2Cl_2 (5 mL) under N_2 . To this was added lutidine (0.78 mL, 6.3 mmols, 3 equiv) and TBSOTf (1 mL, 4.2 mmols, 2 equiv) at 0°C . This was allowed to warm to room temperature and continued to be stirred for 12 h. After this time, the reaction was quenched by addition of NH_4Cl (sat soln). The organic layer was extracted with ethyl acetate and concentrated before being purified over silica gel eluting 1% diethyl ether/hexane to yield 3-(*tert*-Butyldimethylsilyloxy)propyl bromide^[4] as a clear oil (535 mg, quant). ^1H NMR (400 MHz, Chloroform-*d*) δ 3.73 (t, J = 5.7 Hz, 2H), 3.52 (t, J = 6.4 Hz, 2H), 2.03 (tt, J = 6.4, 5.7 Hz, 2H), 0.90 (s, 9H), 0.07 (s, 6H). In agreement with literature.^[4]

Then, under Ar, triphenylphosphine (524 mg, 2 mmol, 2 equiv) was dissolved in dry toluene (1.8 mL). To this was added butyldimethylsilyloxy)propyl bromide (504 mg, 2 mmol, 2 equiv) and refluxed for 24 h. At this point the mixture was cooled and phases allowed to separate. The top layer of toluene was decanted off before addition of THF (2 mL). The vessel was cooled to -20°C and NaHMDS (1M in THF, 3 mL, 3 equiv) was added dropwise. This was allowed to stir for 20 minutes before addition of *p*-methyl benzaldehyde (0.12 mL, 1 mmol, 1 equiv). This was allowed to warm to room temperature and stirred overnight. At this point the reaction was quenched by addition of NH_4Cl (sat soln). The organic layer was extracted with diethyl ether and dried over MgSO_4 . This yielded 100 mg of crude protected homoallylic alcohol which was carried directly into TBAF deprotection.

Protected homoallylic alcohol (80 mg, 0.28 mmol, 1 equiv) was stirred in TBAF (1 M in THF, 1.5 mL, 5 equiv) at rt, under N_2 for 20 min. The reaction was simply concentrated under a stream of N_2 and purified over silica gel 10% EtOAc/ CH_2Cl_2 to yield a mixture of 2.7:1 *Z/E* homoallylic alcohols **2c** (32 mg, 20% over 3 steps).

3. Isomerisation study

3.1 Orbital analysis for isomerisation

Four possible pathways were envisioned for isomerisation from the kinetic *trans*-fused products to the thermodynamic *cis*-fused ones: two oxygens can be protonated and there are two ‘directions’ in which the electrons can flow, either around the sp^3 C-C framework or into the aryl ring. The orbital overlap for the initial interaction of the appropriate oxygen lone pair with the appropriate C-C anti-bonding orbital is good for the *retro* Prins/HDA, oxy Michael and Grob pathways but not for the benzyne pathway:

Consequently, we hypothesized that the *retro* Prins/HDA, oxy Michael and Grob pathways were more likely to be operative.

3.2 Racemisation Study

Analysis for this experiment was carried out by analytical chiral stationary phase HPLC using a Diacel IF column (10 mm x 20 mL) eluting 5% IPA/Hexane at 1 mL/min and visualised at 210 nm.

Both enantiomers of *cis*-fused-**3c** and of *trans*-fused-**3c** were partially resolved under these conditions.

A sample of *cis*-fused-**3c** (*dr* ~1:3) was obtained from the following reaction:

HPLC chromatogram of (±)-*cis*-fused-**3c** (*dr* ~1:3) (Figure S1)

A sample of *trans*-fused-**3c** (*dr* ~5:1) was obtained from the following reaction (*t* = 5 h):

The diastereomeric purity was then increased (to *dr* >20:1) by preparative TLC (20% diethyl ether in petroleum ether).

HPLC chromatogram of (±)-*trans*-fused-**3c** (*dr* >20:1) (Figure S2)

Preparative HPLC was then used to separate the *trans*-fused-**3c** sample into its enantiomers using a Diacel Chiralpak IF column (20 mm diameter x 250 mm), eluting with 5% IPA/Hexane at 18 mL/min with 2.3 mg injected. The slower eluting enantiomer was collected:

HPLC chromatogram of single enantiomer of *trans*-fused-**3c** product (Figure S3)

This single *trans*-fused-**3c** enantiomer was subjected to the reaction conditions for the cyclocondensation reacton: CSA (1.15 mg, 0.005 mmol) in MeCN (0.1 mL) at 50 °C for 12 h. After this time, the solution was eluted through a silica plug and flushed with ethyl acetate to remove CSA before HPLC analysis.

HPLC chromatogram of reaction mixture after 12 h (Figure S4)

To confirm the identity of the two new peaks at 5.85 min and 8.59 min, first homoallylic alcohol **2c** was added to the vial.

HPLC chromatogram of reaction after 12 h spiked with starting homoallylic alcohol **2c** (Figure S5)

The peak at 8.59 min increased indicating its identity as homoallylic alcohol **2c**.

To confirm the identity of the salicylaldehyde (**1**), an authentic sample of this was added to the vial.

HPLC of reaction after 12 h spiked with homoallylic alcohol **2c** and salicylaldehyde (**1**) (Figure S6)

The peak at 5.85 min increased (to saturation) indicating its identity as salicylaldehyde (**1**).

3.3 NMR tracking of isomerisation

The isomerization of *trans*-fused **3c** to *cis*-fused **3c** was monitored by ¹H NMR.

Thus, *trans*-fused-**3c** (*dr* 94:6, 3.3 mg, 0.01 mmol) was weighed into a vial. To this was added CSA (4.6 mg, 0.02 mmol) in d₃-MeCN (0.4 mL) which had been pre heated to 50 °C. This combined mixture was transferred to an NMR tube and placed in a pre-heated NMR spectrometer at 50 °C.

From this, integration of spectra could reveal how distribution of species changed with respect to time. The reaction was observed to be clean with retention of mass balance and so allowed plotting of concentration as a function of time using the initial concentration (Scheme 5, main manuscript)

4. Representative processing of raw spectral data

NMR data was processed using MestReNova. Spectra were automatically phase corrected and baselined (either Whittaker smoother or Ablative). Spectra were stacked and superimposed with characteristic peaks integrated. Raw integration values were then processed in Excel. All integrals were summed together, and a concentration of species was obtained. Below is processing procedure for the isomerisation spectra.

Superimposed ^1H NMR spectra for isomerisation (Figure S7)

Characteristic ^1H NMR peaks of compounds **2c** and **3c** (Figure S8)

The *cis*-fused and *trans*-fused diastereoisomers were assigned by reference to the isolated single diastereomers of **3c** (chemical shift and coupling constant) and by Mass spectrometry.

For tabulated data see **Appendix 1**.

5. Processing data using COPASI

Using COPASI, the experimental data collected for the full reaction courses were taken and modelled. Inputting the reaction progress from ^1H NMR and using the scatter search method with 200 iterations led to curves with good levels of fitting. The lower bound for all reactions was set to zero with an upper bound of infinity. Alternative methods were trialed sequentially to ensure correct best fit identification. As a representation, the isomerization data for the transformation of *trans*-fused-**3c** → *cis*-fused-**3c** is shown below.

The process was modelled as being reversible in both the formation of the *trans*-fused- and *cis*-fused diastereomers. The fitted parameters showed good agreement with the experimental data.

For tabulated data see **Appendix 2**.

6. Procedure for NMR tracking of reactions

In a vial, a stock solution of CSA (9.2 mg, 0.04 mmol) was made in MeCN- d_3 (0.8 mL). This was placed in a preheated oil bath at 50 °C for 10 min. To this was added salicylaldehyde (**1**, 9.4 microliters, 0.09 mmol). From this stock solution 0.4 mL was taken out and transferred into an NMR tube containing homoallylic alcohol **2** (0.04 mmol). This was then immediately transferred into an NMR spectrometer which had been preheated to 50 °C. The first spectrum was recorded after 3.5 min from addition of starting materials into NMR tube (time required to load sample, lock, shim etc). Spectra were then taken continuously (1 every minute followed by one every 10 min for 12 h).

The reactions were observed to be clean with retention of mass balance. This allowed the concentration to be plotted as a function of time using the initial concentration. This data was then processed as outlined in section 4. For tabulated data see **Appendix 3**.

Graphs of experimental data from ^1H NMR with fitted COPASI parameters from data obtained as in section 5 overlaid (Figure S12)

7. Initial rate Hammett plot

For the Hammett plot, conversion was calculated as the consumption of the starting homoallylic alcohol **2** and taken to 20% for the initial rate (or for the 13 h period in the case of **2f** to reach 14% conv.). At low conversions the isomerisation was assumed to be negligible. A line of best fit was taken for these points and displayed in fig with R^2 shown indicating good linearity in all reactions. These initial rates were then divided by k_H , the logarithm taken and plotted against known sigma plus values^[5] to yield the Hammett plot as shown in Figure S14 (below).

8. COPASI modelling for Hammett plot

Using COPASI, the experimental full reaction course data collected for the six reactions were taken and modelled. Inputting the reaction progress from ¹H NMR and using the scatter search method with 200 iterations led to curves with good levels of fitting. The lower bound for all reactions was set to zero with an upper bound of infinity. Alternative methods were trialled sequentially to ensure correct best fit identification. The start point was not randomised to ensure sequential optimisation. Optimisation was repeated until the best value was found and global minimum was confirmed by altering parameters and observing alternative local minimum. Initially, both the formation of *cis*-fused- and *trans*-fused diastereomers of **3** were modelled as reversible reactions and this resulted in the following results. The readout was overlayed with the experimental data to verify the accuracy of the fitting.

Modelling was also carried out assuming that the formation of the *trans*-fused diastereomer **3** was reversible but the formation of *cis*-fused diastereoisomer **3** was *irreversible*. This was done to mirror the experimental observation that reversion of *cis*-fused products **3** back to starting materials never

occurred (fitted graphs with experimental NMR data not shown). This alternative method of modelling yielded comparable results to that which assumed all reactions are reversible but gave a marginally poorer R^2 fit. Both modelling methods indicated a notable difference in ρ^+ between the formation of the *cis*-fused- and *trans*-fused products **3**. Only the all-reversible derived data is reported in the main manuscript as irreversibility is usually reserved for reactions leading to gas formation.

9. DFT modelling

All DFT results including computed structures *etc.* can be found in the FAIR Data Archive (DOI: [10.14469/hpc/3943](https://doi.org/10.14469/hpc/3943)) and sub-collections therein.

As discussed in the main manuscript, inspection of the HOMO in the *endo* TSs suggested π - π stacking being significant in the more electron rich TSs and less so in the more electron deficient TSs. This is also evident from inspection of their NCI surfaces (Figures S21-22).

Computed NCI of the *endo* TS¹ (*p*-NH₂ NCI) showing a significant attractive interaction surface (Figure S21)

Computed NCI of the *exo* TS¹ (*p*-NH₂ NCI) showing a minimal interaction surface (Figure S22)

To corroborate our experimental Hammett analysis, we sought a comparison with a computed value. Key numbers have been extracted from Gaussian files and are reported here. For Gaussian files, the FAIR Data Archive, the relevant ending of DOIs are listed in the table. To extend the range of Hammett analysis we computed energies for reactions using homoallylic alcohols **2** with a wider range of substituents than experimentally, namely *p*-NH₂, *p*-OMe (**2a**), *p*-H (**2e**), *p*-Cl (**2f**), *p*-CN and *p*-NO₂.

Inspection of the Gibbs free energy of the *trans*-fused *p*-CN and *p*-NO₂ products suggested that these reactions would be endergonic and therefore unfeasible (as shown in table S5). As such they were not included in our Hammett analysis. Values for σ^+ were taken from ref. 5.

10. Determination of the optimal quantity of HFIP

The reaction to form products **3c** was used to evaluate the effect of HFIP as an additive in CDCl_3 as solvent for these reactions:

To an NMR tube was added homoallylic alcohol **2c** (6.5 mg, 0.04 mmol, 1 equiv). CSA (4.6 mg, 0.02 mmol, 0.5 equiv) was solubilised in CDCl_3 and HFIP of varying amounts to make up a total volume of

0.4 mL. To this solution salicylaldehyde (**1**, 4.7 μ L, 0.044 mmol, 1.1 equiv) was added and transferred to the NMR tube. A ^1H NMR was taken after 10 min and analysed to identify optimal conditions. 12 equivalents of HFIP was found to be optimal.

Bar chart to show effect of number of equiv. of HFIP on the conversion of **2c** $\rightarrow$ **3c** after 10 min (Figure S26)

11. NMR tracking of reactions using HFIP as an additive

In a vial, a stock solution of CSA (13.8 mg, 0.06 mmol) was made in chloroform-*d* (1.05 mL) and HFIP (0.15 mL). To this was added salicylaldehyde (13.3 μ L, 0.13 mmol). From this stock solution 0.6 mL was taken out and transferred into an NMR tube containing homoallylic alcohol (0.06 mmol). This was then immediately transferred into an NMR spectrometer. The first spectrum was recorded after 3.5 min from addition of starting materials into NMR tube (time required to load sample, lock, shim etc). The reaction was monitored by NMR and quenched by addition of NaHCO_3 (sat. soln.) after the stated time. The organic layer was extracted with CH_2Cl_2 , dried over anhydrous Na_2SO_4 and concentrated under a stream of N_2 . The product was isolated by flash column chromatography 25% diethyl ether/petroleum ether.

COPASI was used to model these reactions, again assuming all steps are reversible.

12. Homoallylic alcohol alkene scrambling experiments

Two experiments were performed. In the first, homoallylic alcohol **2c** was treated with CSA in CDCl₃ with HFIP (12 equiv.) in the presence of salicylaldehyde (**1**) to see if isomerization occurred during furanochromane formation. In the second, salicylaldehyde (**1**) was not added to see if isomerization occurred just upon subjecting the homoallylic alcohol to the CSA in CDCl₃ with HFIP (12 equiv.).

Reaction in presence of salicylaldehyde (1):

(*E/Z*)-4-(*p*-Tolyl)but-3-en-1-ol (Z/E = 2.7/1) **2c** (6.5 mg, 0.04 mmol, 1 equiv) was weighed into an NMR tube. In a separate vial, CSA (4.6 mg, 0.02 mmol, 0.5 equiv) was dissolved in 0.05 mL HFIP and 0.35 mL CDCl₃. To this vial, was added salicylaldehyde **1** (4.4 μ L, 0.04 mmol, 1.1 equiv). This was then transferred to an NMR tube and subjected to ¹H NMR analysis. Within 15 min, inspection of the ¹H NMR revealed complete consumption of the alkene in the presence of salicylaldehyde. This reaction was then quenched by addition of the NaHCO₃ (sat. soln.), extracted with CH₂Cl₂ and analysed by ¹H NMR to show a 1.4:1 mixture of *cis*-fused-3a,4-**7** and *cis*-fused-3a,4-**3c**.

Reaction in absence of salicylaldehyde (**1**):

As for the above reaction but using 0.02 mmol of homoallylic alcohol and 0.02 mmol of CSA dissolved in 0.05 mL HFIP and 0.35 mL CDCl₃, 2-Tolyl-tetrahydrofuran was cleanly formed (70% conversion after 5 h) with the ratio of unreacted *E/Z* isomers of the starting homoallylic alcohol **2c** remaining unchanged.
