1. Experimental Procedure

Chemicals and Regents

Degussa P25 was purchased from Shanghai Haiyi Co., Ltd. Potassium hydroxide (KOH, 90%), hexamethylenetetramine (HMTA, 99%), L-ascorbic acid (AA, AR), methanol (CH₃OH, AR), tetrachloroauric (III) acid tetrahydrate (HAuCl₄·4H₂O, AR) and isopropyl alcohol (IPA, AR) were received from Sinopharm Chemical Reagent Co., Ltd. Sodium tetrachloropalladate (II) (Na₂PdCl₄, 98%) was received from Kunming Institute of Precious Metals. Polyvinylpyrrolidone (PVP, MW=8000, AR) were obtained from Alfa Aesar Co., Ltd. All chemicals and regents were used as received without further treatment. Ultrapure water was used in all experiments.

Synthesis of Anatase TiO₂ with Exposed {101} and {001} Facets

{101} and {001} facets co-exposed TiO₂ nanocrystals (NCs) were synthesized via a two-step hydrothermal reaction reported by our group.^{1, 2} Firstly, Degussa P25 (2.0 g) and KOH (44.8 g) were dispersed in ultrapure water (80 mL) and stirring for 30 min under room temperature. The mixture was divided into three equal parts and transferred to three 50 mL Teflon-lined autoclaves, followed by the hydrothermal treatment at 200 °C for 24 h. The resultant potassium titanate nanowires (KTNWs) were washed and centrifuged with ultrapure water until the supernatant showed neutrality. Secondly, anatase TiO₂ with exposed {101} and {001} facets were prepared by using KTNWs and HMTA as precursor and shape regulator, respectively. Typically, KTNWs (10 mg) were dispersed in ultrapure water (3 mL) to form a white suspension under intense ultrasonic treatment over 30 min. HMTA (2.1 g) dissolved in ultrapure water (3 mL) were added into above white suspension and vigorously stirred for another 30 min. The mixture was transferred to 25 mL Teflon-lined autoclaves and was kept at 200 °C for 12 h. Finally, the target TiO₂ was collected by successive washing and drying procedures.

Deposition of Au-Pd Alloy Nanoparticles (NPs) on TiO₂ Facets

Non-selective deposition on {101} and {001} facets

Au-Pd alloy NPs (total mass fraction of Au and Pd =1wt %, Au/Pd molar ratio of 1:1) were synthesized and supported on TiO₂ via chemical reduction method by using AA as reducing agent. TiO₂ powder (20 mg), PVP (30 mg) and AA (80 mg) were dispersed in ultrapure water (20 mL) after an ultrasonic treatment for 10 min to form a homogeneous mixture. To this suspension were added dropwise the desired volume of HAuCl₄ (1g L⁻¹) and Na₂PdCl₄ (1g L⁻¹) mixed solution (See Table S1 for volume details of HAuCl₄ and Na₂PdCl₄ solutions), followed by stirring in a 60 °C water bath for 4 h. Finally, the samples were washed with ethanol and water for several times and dried in a vacuum oven overnight.

Selective Deposition on {001} Facets

For realizing the selective deposition of Au-Pd alloy (total mass fraction of Au and Pd =1wt %, Au/Pd molar ratio of 1:1) on {101} facets, photo-irradiation reduction was conducted in this experiment segment. Typically, TiO₂ powder (20 mg) and PVP (30 mg) was ultrasonic dispersed in methanol solution (30 mL, 30 vol %), followed by the injection of desired volume of HAuCl₄ (1g L⁻¹) and Na₂PdCl₄ (1g L⁻¹) mixed solution. Then, the slurry underwent an UV light irradiation set-up (average light density 5.3 mW cm⁻²) under room temperature for 2 h to complete this reduction process. Finally, the samples were washed with ethanol and water for several times and dried in a vacuum oven overnight. In order to synthesize AuPd alloy with various element molar ratio, different volumes of Au and Pd precursors were employed with fixing the total metal mass percentage of ~1 wt. % for both mono- and bi-metallic Au-Pd loaded TiO₂ (See Table S1 for volume details of HAuCl₄ and Na₂PdCl₄ solutions).

Characterizations of Materials

The surface morphologies of as-prepared TiO₂ were characterized by a scanning electron microscope (SEM, Hitachi S-4800). All samples for the TEM analysis were investigated on a transmission electron microscope (TEM, Hitachi 7700) and a high resolution transmission electron microscope (HR-TEM, JEM 2010E) with an accelerating voltage of 200 kV. The high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM) and energy dispersive X-ray spectroscopy (EDX) elemental mapping were performed with a FEI TECNAI F30 microscope operated at 300 kV. The crystal phase of products was determined by powder X-ray diffraction (XRD) using a Rigaku Ultima IV X-ray diffractometer with Cu K α radiation. Mass spectrometer (MS, Agilent 5975c) was employed to confirm the carbon source of hydrocarbons, by using ¹³CO₂ (Sigma-Aldrich, 99% atom ¹³C) as feeding gas. The surface states and chemical compositions of products were analysed using X-ray photoelectron spectroscopy (XPS, ESCALAB 250Xi, Thermo Scientific). All binding energies were calibrated using the contaminant carbon (C1s= 284.6 eV). UV–visible diffuse reflectance spectra (UV-Vis DRS) were obtained on a Hitachi U-3010 UV-vis spectrophotometer with BaSO₄ as reference. The steady state photoluminescence (PL) and time resolved photoluminescence (TR-PL) spectra were recorded by utilizing the fluorescence spectrophotometer (Edinburgh, FLSP920) with an excitation wavelength of 230 nm under room temperature. Surface photovoltage (SPV) spectroscopy was recorded on a self-made instrument, with the raw data normalized by an illuminometer (Zolix UOM-1S). CO₂ adsorption isotherms were collected on a Micrometrics (ASAP 2010V5.02H) surface area analyser. The samples were degassed in vacuum at 120 °C for 12 h and then measured in 0 °C ice-water bath. *In situ* diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) was tested on an infrared spectrometer (BRUKER VERTEX 70), in which a 300 W Xe lamp was employed as light source. The baselines are

deducted from all spectra to exclude environment factors, and the bands of KBr in the presence of CO₂ and water vapor under light irradiation are set as reference. The actual mass fractions of Au and Pd elements in the composite photocatalysts were determined by inductively coupled plasma atomic emission spectrometry (ICP-AES, Baird PS-4).

Photoelectrochemical Measurements

Photoelectrochemical properties of samples were investigated on an electrochemical workstation (CHI-660D, China) equipped with three-electrode system. In a typical experiment, a platinum wire and saturated calomel electrode were employed as counter electrode and reference electrode, respectively. A 300 W Xe lamp was utilized as the light source. CO₂ saturated NaHCO₃ aqueous solution (0.1 mol L⁻¹) was served as electrolyte. For the fabrication of working electrode, photocatalyst (10 mg) was homogeneously dispersed in isopropyl alcohol (1 mL). The suspension was drop-coating on an indium tin oxide conducting (ITO) glass and naturally dried under ambient condition. The transient photocurrent responses were obtained under Xe lamp with the light chopped manually at regular intervals. Linear sweep voltammetry (LSV) with a scan rate of 10 mV s⁻¹ were measured under uninterrupted irradiation.

Photocatalytic CO₂ Reduction

The CO₂ photoreduction was carried out in a commercial evaluation system equipped with a quartz cell (total volume of 150 mL) via vapor-solid reaction mode. Powder photocatalyst (10 mg) was sampled and evenly coated on a piece of quartz plate (2.5*3.5 cm²). This plate was intentionally pretreated in a long-term vacuum drying process (150 °C, 12 h) and UV light irradiation (light intensity of 5.3 mW cm⁻²) for 2 h to remove the residual water and organic contaminants, respectively. This plate was vertically placed in the reaction cell. Ultra-pure water (0.1 mL) as proton source was injected into quartz cell. Then entire reaction setup was sealed and

vacuum degassed for several times, followed by high-purity CO₂ filled into the reactor to reach a pressure at 0.26 MPa. Prior to light illumination (300 W Xe lamp, light intensity of 853 mW cm⁻²), the reactor stored in dark was heated to 40 °C accompanied by continuously stirring for 1 h to ensure an adsorption-desorption equilibrium of CO₂ and aqueous vapor over photocatalysts. The gas-phase products were collected every hour and analyzed online by gas chromatography (KECHUANG GC 2002, China). Argon (Ar) gas was used as carrier gas. The amounts of hydrocarbons were determined using a flame ionization detector (FID). Carbon monoxide (CO) was converted to methane (CH₄) in methanation reactor and then detected by FID. The amount of hydrogen (H₂) was analyzed via a thermal conductivity detector (TCD). To evaluate the efficiency of CO₂ reduction, we can calculate the selectivity (Sel.) by adding up the reacted electrons towards specific reduction products³ as follows:

Equation S1:

$$\text{Sel. of hydrocarbons} = \frac{n(\text{CH}_4) * 8 + n(\text{C}_2\text{H}_4) * 12 + n(\text{C}_2\text{H}_6) * 14}{n(\text{CH}_4) * 8 + n(\text{C}_2\text{H}_4) * 12 + n(\text{C}_2\text{H}_6) * 14 + n(\text{CO}) * 2 + n(\text{H}_2) * 2}$$

2. Supplementary results and discussion

Table S1. The detailed volume of HAuCl_4 and Na_2PdCl_4 solutions in preparing samples.

Samples	$\text{HAuCl}_4(\text{v/uL})$	$\text{Na}_2\text{PdCl}_4(\text{v/uL})$
CR-Au ₁ Pd ₁	270	194
PD-Au	418	0
PD-Au ₈ Pd ₁	395	30.5
PD-Au ₆ Pd ₁	382	45.8
PD-Au ₄ Pd ₁	368	66
PD-Au ₂ Pd ₁	330	117
PD-Au ₁ Pd ₁	270	194
PD-Au ₁ Pd ₄	132	378
PD-Pd	0	555

Table S2. ICP-AES results of as-prepared samples.

Samples	Noble metal elements (/ wt. %)			Molar ratio (n_{Au} : n_{Pd})
	Au	Pd	Au + Pd	
CR-Au ₁ Pd ₁	0.65	0.33	0.98	1.05
PD-Au	0.95	/	0.95	/
PD-Au ₈ Pd ₁	0.94	0.06	1.00	8.51
PD-Au ₆ Pd ₁	0.89	0.09	0.98	5.41
PD-Au ₄ Pd ₁	0.87	0.12	0.99	3.83
PD-Au ₂ Pd ₁	0.78	0.20	0.98	2.05
PD-Au ₁ Pd ₁	0.62	0.33	0.95	1.02
PD-Au ₁ Pd ₄	0.30	0.68	0.98	0.24
PD-Pd	/	0.97	0.97	/

Table S3. Summary of noble metal(s)/TiO₂ materials for photocatalytic CO₂ reduction under similar catalytic conditions.

Photocatalysts	Reduction products (μmol g ⁻¹ h ⁻¹)					Sel. of hydrocarbons ^a	References
	CH ₄	C ₂ H ₄	C ₂ H ₆	CO	H ₂		
PD-Au₆Pd₁	12.7	0.7	0.8	10.9	0	85%	This work
Au-Pd/3DOM-TiO ₂	18.5	0	0	1.2	18.6	79%	(4) ⁴
Au/PC500 TiO ₂	8	0	1	2	9.5	77%	(5) ⁵
PdH _{0.43} /TiO ₂ nanosheets	20.5	0	0	4.5	45	62%	(6) ⁶
Cu/Pt/TiO ₂ -5h	33	0	0	8.3	25	80%	(7) ⁷
3.0% MgO-Pt-TiO ₂	6.3	0	0	0.02	5.1	83%	(9) ⁸
0.5Pt/TiO ₂ -COK-12	10.6	0	0	0	55.56	43%	(8) ⁹
Au@TiO ₂ -20-Au	0.833	0	0	0.67	8.33	27%	(10) ¹⁰

^a The sel. of hydrocarbons was calculated by adding up the reacted electrons towards specific reduction products as follows:

Equation S1:

$$\text{Sel. of hydrocarbons} = \frac{n(\text{CH}_4) * 8 + n(\text{C}_2\text{H}_4) * 12 + n(\text{C}_2\text{H}_6) * 14}{n(\text{CH}_4) * 8 + n(\text{C}_2\text{H}_4) * 12 + n(\text{C}_2\text{H}_6) * 14 + n(\text{CO}) * 2 + n(\text{H}_2) * 2}$$

As shown in Table S3, through the comparison with those noble metal(s)/TiO₂-based photocatalysts under similar catalytic conditions reported by literatures, our as-prepared PD-Au₆Pd₁ shows advantages in the following three aspects: (i) the higher sel. of hydrocarbons fuels, (ii) the obviously suppressed side reaction, such as hydrogen evolution, and (iii) a certain amount of C₂H₄ and C₂H₆ were detected, but rare in the references cited above.

Table S4. A examine of photogenerated electron-hole balance in PD-Au₆Pd₁.

	Reduction products				Oxidation products	Electron-hole balance ^a
Evolution rate	CH ₄	CO	C ₂ H ₄	C ₂ H ₆	O ₂	N _e ⁻ /N _h ⁺
($\mu\text{mol g}^{-1} \text{h}^{-1}$)	12.78	10.76	0.73	0.79	35.36	1.02

^a The electron-hole balance was evaluated by the ratio of $[8n(\text{CH}_4) + 2n(\text{CO}) + 12n(\text{C}_2\text{H}_4) + 14n(\text{C}_2\text{H}_6)]$ amounts to $[4n(\text{O}_2)]$ amounts.

Figure S1. (a) SEM image and the corresponding structural model (Insets) and (b) XRD pattern of {101} and {001} facets co-exposed TiO₂.

As shown in Figure S1a, the as-prepared TiO₂ are enclosed by two {001} on the top/bottom and eight {101} facets on the side surface, exhibiting a well-defined truncated tetragonal bipyramidal morphology. The corresponding XRD pattern (Figure S1b) indicates the pure anatase phase TiO₂ (JCPDS *no.* 21-1272) without any other impurities can be obtained in this case.

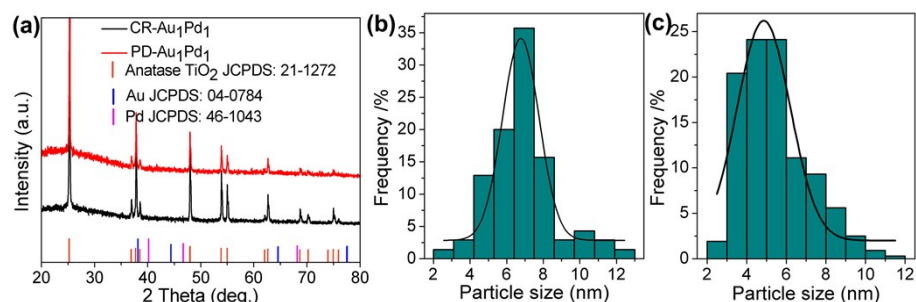

Figure S2. (a) XRD pattern and the size distribution of Au-Pd alloy particles loaded on (b) CR-Au₁Pd₁ and (c) PD-Au₁Pd₁, respectively.

As shown in Figure S2a, the absence of characteristic diffraction peaks belonging to Au and Pd components may probably be due to the extremely low loading amount of Au₁Pd₁ on TiO₂. Figure S2b and c show the size distribution of Au₁Pd₁ nanoparticles on CR-Au₁Pd₁ and PD-Au₁Pd₁, which are statistically derived from Figure 1a and e, respectively.

Figure S3. TEM images of mono- or bi-metallic Au-Pd loaded TiO₂ series samples. (a) PD-Au, (b) PD-Au₈Pd₁, (c) PD-Au₆Pd₁, (d) PD-Au₄Pd₁, (e) PD-Au₂Pd₁, (f) PD-Au₁Pd₁, (g) PD-Au₁Pd₄ and (h) PD-Pd.

As shown in Figure S3, several alloy nanoparticles with varying Au to Pd stoichiometric ratios (1:0, 8:1, 6:1, 4:1, 2:1, 1:4, 0:1) were uniformly loaded on the TiO₂ {101} facets.

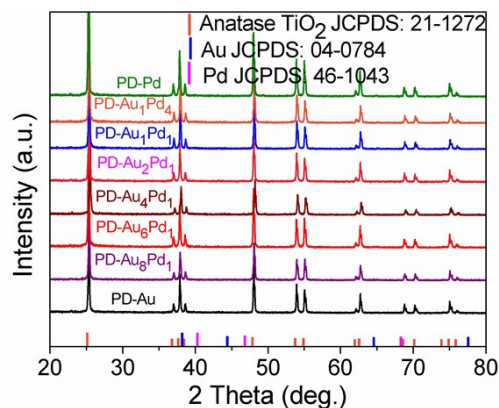

Figure S4. XRD patterns of mono- or bi-metallic Au-Pd loaded TiO_2 series samples.

Similar to Figure S2a, XRD result in Figure S4 fails to detect the diffraction peaks of Au or Pd species owing to their extremely low loading amounts (~ 1 wt. %).

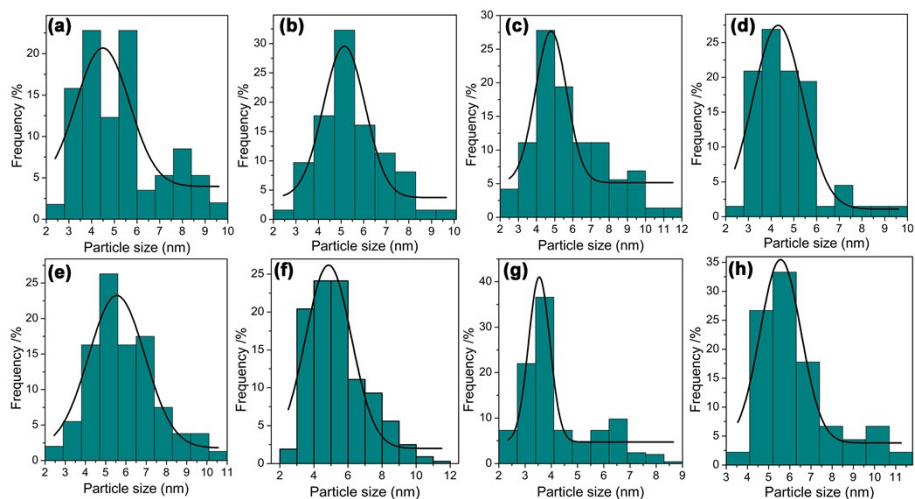

Figure S5. Size distribution of mono- or bi-metallic Au-Pd nanoparticles calculated from the corresponding TEM images in figure S3. (a) PD-Au, (b) PD-Au₈Pd₁, (c) PD-Au₆Pd₁, (d) PD-Au₄Pd₁, (e) PD-Au₂Pd₁, (f) PD-Au₁Pd₁, (g) PD-Au₁Pd₄ and (h) PD-Pd.

As shown in Figure S5, alloy nanoparticles with varying Au to Pd stoichiometric ratios (1:0, 8:1, 6:1, 4:1, 2:1, 1:4, 0:1) loaded on the TiO_2 {101} facets had similar size distribution, well eliminating the size effect of the co-catalyst.

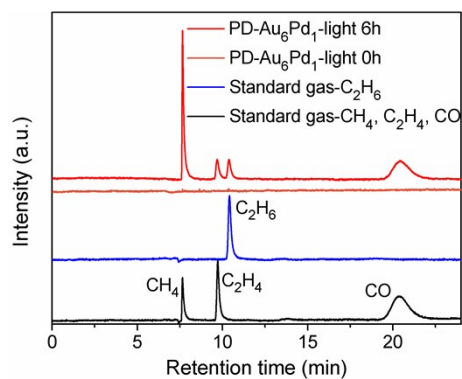

Figure S6. A typical gas chromatograph trace of the generated carbon-based products on PD-Au₆Pd₁.

Figure S7. Results of MS analysis for produced CH₄ using ¹²CO₂ and ¹³CO₂ as gas sources, respectively.

As shown in Figure S7, ¹³CH₄ (m/z = 17) was detectable when ¹³CO₂ was employed as feeding gas, which provided solid proof for the carbon source of hydrocarbons.

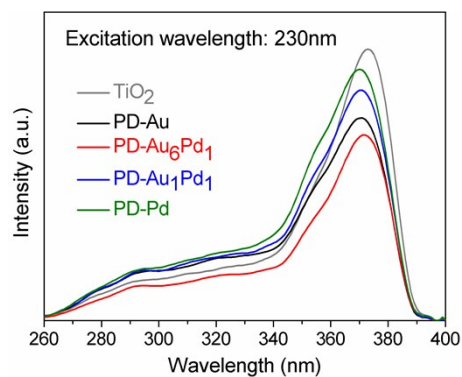

Figure S8. Steady state PL spectroscopy of TiO_2 , PD-Au, PD-Pd, PD- Au_1Pd_1 and PD- Au_6Pd_1 .

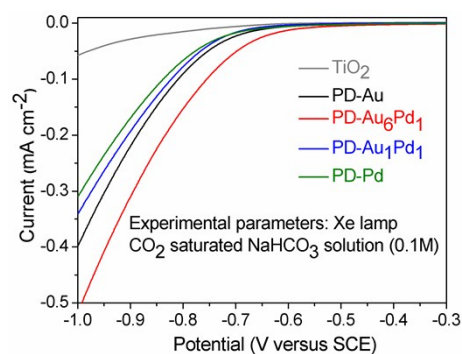

Figure S9. LSV curves conducted in CO_2 saturated NaHCO_3 aqueous solution under Xe lamp irradiation.

Figure S10. A schematic illustration of the possible structures of CO_2^{*-} species adsorbed on the surface of catalysts.

Figure S11. (a) The time-dependent O₂ yields and (b) the evolution rate of reduction (CH₄, CO, C₂H₄, and C₂H₆) and oxidation (O₂) products on PD-Au₆Pd₁.
