**General remarks.** All manipulations were carried out under dry nitrogen using standard Schlenk and glovebox techniques. Solvents were distilled from appropriate drying agents and stored under N<sub>2</sub> in Schlenk tubes equipped with J. Young-type Teflon stoppers and containing activated molecular sieves (4 Å). Microanalyses were carried out with a LECO CHNS-932 analyser. NMR spectra were recorded on Bruker 400 and 500 spectrometers in C<sub>6</sub>D<sub>6</sub> at 298 K unless otherwise stated, using standard TOPSPIN 4.0 software. <sup>1</sup>H NMR and <sup>13</sup>C{<sup>1</sup>H} NMR chemical shifts are referenced to residual protons or carbons in deuterated solvent. Chemical shifts ( $\delta$ ) are given in ppm and coupling constants ( $J$ ) in Hz. All reagents were purchased from the usual commercial suppliers. Compounds CH(N*i*Pr)<sub>2</sub>BC<sub>8</sub>H<sub>14</sub> (**2**) and CH(N*i*Pr)<sub>2</sub>(C<sub>8</sub>H<sub>14</sub>BHBC<sub>8</sub>H<sub>14</sub>) (**3**) were prepared according to literature procedures.<sup>1</sup>

## Catalytic reactions

### General procedure for the hydroboration reaction.

**NMR scale:** In a glovebox, the corresponding carbodiimide (0.20 mmol) was dissolved in 600 μL of C<sub>6</sub>D<sub>6</sub>. Then, pinacol borane (HBpin, 30 μL, 0.20 mmol) was added to the solution, followed by addition of a measured volume of a stock solution of 9-borabicyclo[3.3.1]nonane dimer [(H-BBN)<sub>2</sub>, 0.10 M in C<sub>6</sub>D<sub>6</sub>]. The final catalyst load, as well as the reaction time and temperature for each reaction are collected in table S1 (*vide infra*). The reaction progress was monitored by <sup>1</sup>H and <sup>11</sup>B NMR spectroscopy until reaction completion. The NMR spectra obtained were then compared with those reported in the literature for the corresponding borylamidines.<sup>2</sup> Conversions were determined by <sup>1</sup>H NMR spectroscopy based on the ratio of the limiting reagent and the target borylamidine product (**1a-h'**). The reactions with the different commercial carbodiimides and HBpin were also performed in the absence of catalyst under the same conditions (see table S1 and Figure S1), to confirm that either negligible or only trace amounts of the target products were obtained.

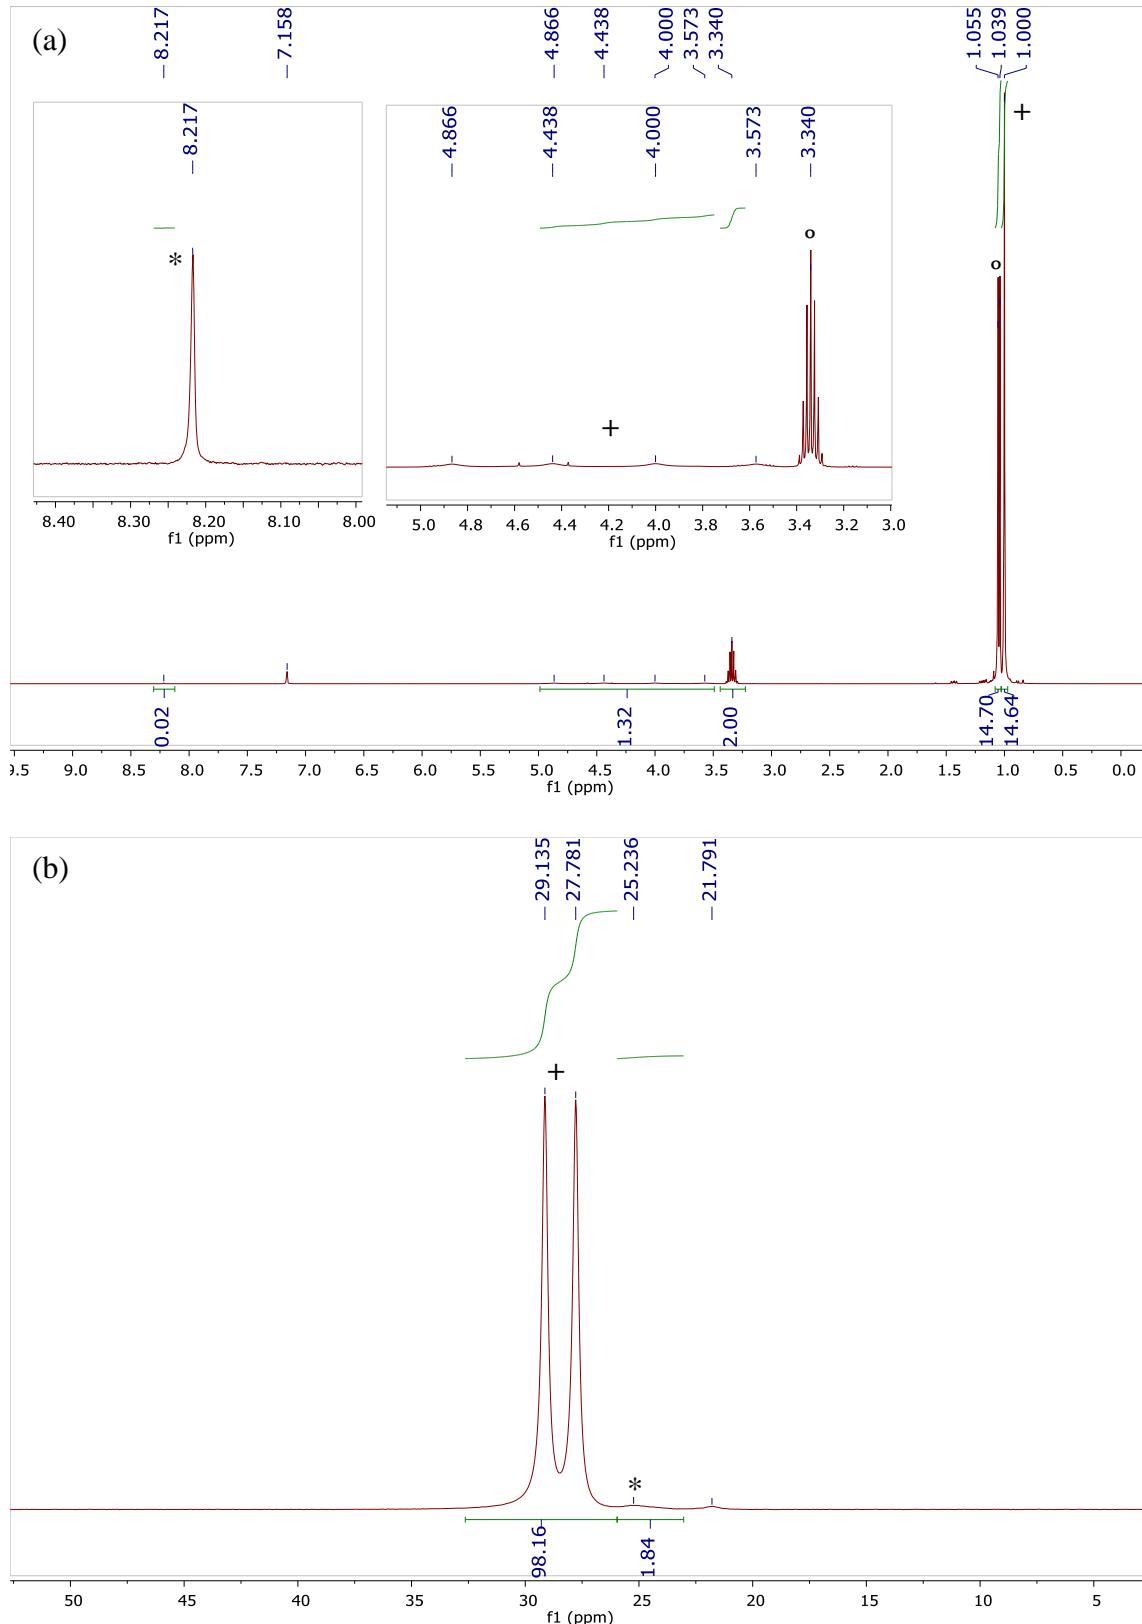

**Table S1.** Monohydroboration of carbodiimides ( $\text{RNCNR}'$ , 0.20 mmol) with HBpin (0.20 mmol) using  $(\text{H-BBN})_2$  as catalyst (NMR scale).

**Kinetic studies.** All kinetics experiments were performed in a similar fashion. In order to determine the *pseudo*-order in [carbodiimide], C(NDipp)<sub>2</sub> (36 mg, 0.10 mmol) was dissolved in ca. 400  $\mu$ L of C<sub>6</sub>D<sub>6</sub>. Then, HBpin (150  $\mu$ L, 1.00 mmol) and the internal standard, tetrakis(trimethylsilyl)silane (TKS, 50  $\mu$ L of a 0.2 M solution in C<sub>6</sub>D<sub>6</sub>, 0.01 mmol) were added to the latter solution, followed by the appropriate volume of catalyst, (H-BBN)<sub>2</sub> (0.025 M stock solution in C<sub>6</sub>D<sub>6</sub>), or compound **4** (0.05 M stock solution in C<sub>6</sub>D<sub>6</sub>). The typical catalyst loads were 0.5-2.5 mol% for (H-BBN)<sub>2</sub> and 1.0-5.0 mol% for compound **4**. The solution was then transferred to a J. Young-NMR tube and the final volume was made up to 0.8 mL (i.e. [C(NDipp)<sub>2</sub>]<sub>0</sub> = 0.125 M; [HBpin]<sub>0</sub> = 1.25 M). The sample was taken out of the glovebox, frozen immediately in a cold acetone bath and subsequently introduced in the NMR spectrometer, set at 25 °C. The reaction was followed by <sup>1</sup>H NMR, collecting data after fixed intervals of time (15 – 300 s) up to, at least, four half-lives. To determine the *pseudo*-order in [HBpin], an analogous procedure was followed, but inverting the reagents' concentration (i.e. [C(NDipp)<sub>2</sub>]<sub>0</sub> = 1.25 M; [HBpin]<sub>0</sub> = 0.125 M). A blank experiment without HBpin was also conducted to ascertain the origin of the induction period in the reactions using (H-BBN)<sub>2</sub> as catalyst (*vide infra*).

**X-ray crystal determination.** X-ray data collection for compounds **1c** and **4** was performed on an Oxford Diffraction Xcalibur Nova single crystal diffractometer at 155 K (**1c**) or 136 K (**4**), using Cu K $\alpha$  radiation. Images were collected at a 62 mm fixed crystal-detector distance using the oscillation method, with 1.1° (**1c**) and 1.2° (**4**) oscillation and variable exposure time per image [2.5-7.5 s (**1c**) and 11.0-60.0 s (**4**)]. Data collection strategy was calculated with the program CrysAlis Pro CCD,<sup>3</sup> and data reduction and cell refinement was performed with the program CrysAlis Pro RED.<sup>3</sup> An empirical absorption correction was applied using the SCALE3 ABSPACK algorithm as implemented in the program CrysAlis Pro RED.<sup>3</sup> Using the program suite WINGX,<sup>4</sup> the structure was solved by SUPERFLIP and refined with full-matrix least squares on  $F^2$  using SHELXL2016.<sup>5</sup> Positional parameters and anisotropic temperature factors for all non-H atoms were refined anisotropically, and all hydrogen atoms were geometrically placed and refined using a riding model.

**DFT calculations.** All the calculations were carried out by using the Gaussian09 suite of programs.<sup>6</sup> The M05–2X functional of Truhlar and co-workers<sup>7</sup> was employed to optimize all the equilibrium structures (catalysts, intermediates and transition states). This functional was parametrized for organic systems with non-covalent interactions and proved to be efficient and reliable for investigating reaction mechanisms. In particular, Cantat and co-workers have recently demonstrated the accuracy of this functional for the computation of reaction mechanisms for the metal-free reduction of CO<sub>2</sub> using highly related guanidines and amidines,<sup>8</sup> and we used extensively for the calculation of reaction mechanisms in the carbodiimide catalyzed reduction of CO<sub>2</sub> with H-BBN or BH<sub>3</sub>.<sup>1</sup> The 6–31G\* split-valence basis set of Pople and co-workers was used for all the atoms.<sup>9</sup> Geometry optimizations were performed under no symmetry restrictions, and frequency analyses were performed for all the stationary points to ensure that minimum structures with no imaginary frequencies were achieved. Transition states were optimized through the Synchronous Transit-Guided Quasi-Newton (STQN) Method as implemented in Gaussian, with the initial guess structures derived in general from previous *relaxed* potential energy surface scans using single and multiple internal coordinates. The corresponding transition states were characterized by frequency analysis (one imaginary frequency) and their connectivity was typically corroborated through Intrinsic-Reaction-Coordinate (IRC) calculations, or when the PES around the TS was relatively flat through manual displacement of atomic coordinates along the imaginary frequency and re-optimization of the resulting structure. The free energies were calculated within the harmonic approximation for vibrational frequencies.
