(A) Typical experimental procedure

To an oven-dried undivided three-necked bottle (10mL) were added substrates **1a** aniline (0.3 mmol), phenothiazine (1.2 equiv) , Bu_4NPF_6 (0.3 mmol) and CH_3CN (10 mL), The bottle was equipped graphite rod(ϕ 6 mm, about 18 mm immersion depth in solution) as the anode and pt plate (10 mm \times 10 mm \times 1 mm) as the cathode. The reaction mixture was stirred and electrolyzed at a constant current of 10 mA under room temperature for 3 h (Figure S1). and stopped until complete consumption of aniline (monitored by TLC). After the reaction was finished, the reaction mixture was concentrated in vacuum, and the resulting residue was purified by silica gel column chromatography (hexane/ethyl acetate) to afford the desired product **3aa**.

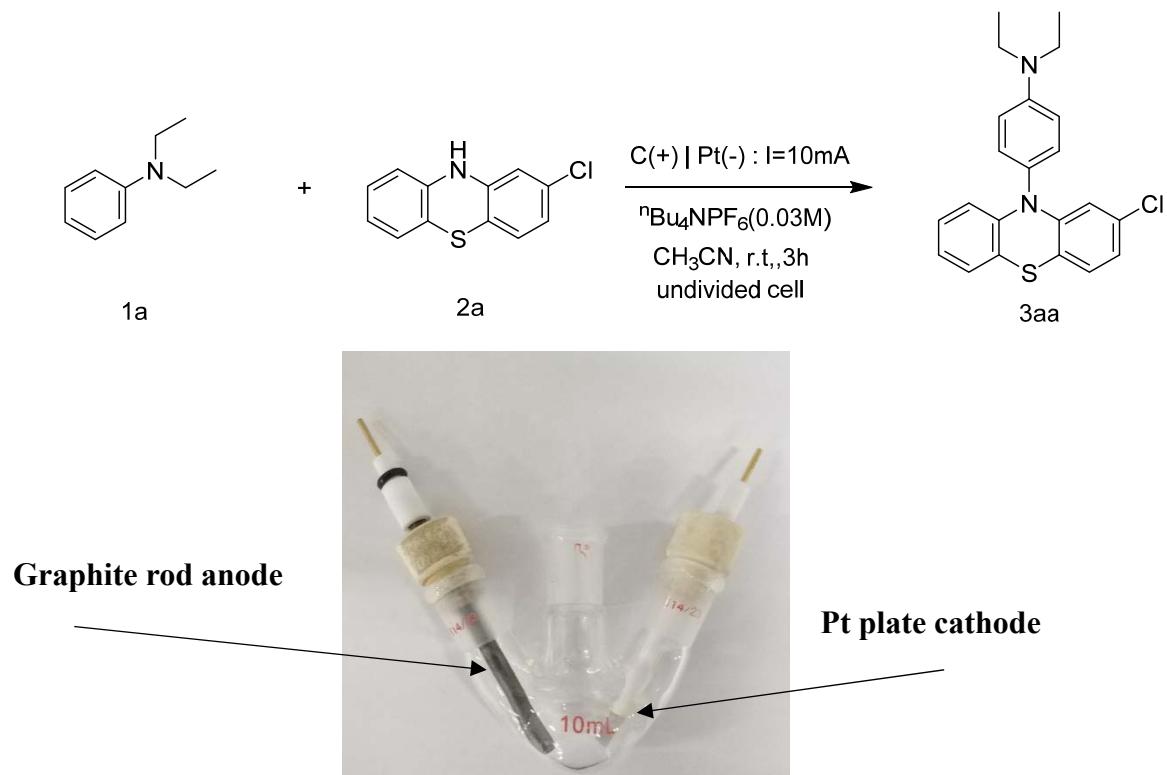

Figure S1. Undivided cell for current controlled electrolysis

Procedure for cyclic voltammetry (CV): Cyclic voltammetry was performed in a three-electrode cell connected to a schlenk line under nitrogen at room temperature. The working electrode was a steady glassy carbon disk electrode while the counter electrode was a platinum plate. The reference was an Ag/AgCl electrode submerged in saturated aqueous KCl solution, and separated from reaction by a salt bridge. 10 mL solvent containing 0.3 M ${}^n\text{Bu}_4\text{NPF}_6$ were poured into the electrochemical cell in cyclic voltammetry experiments. The CV of all substrates were measured at the concentration of 0.01M. The scan rate was 0.10 V/s, ranging from 0 V to 2.0 V.
