Ammonia-assisted Fast Li-ion Conduction in
A New Ammine Lithium Borohydride, LiBH₄-½NH₃

Yigang Yan, Jakob B. Grinderslev, Young-Su Lee, Mathias Jørgensen, Young Whan Cho, Radovan Černý, Torben R. Jensen*

Electronic Supplementary Information (ESI)

Experimental Methods:

Chemicals of LiBH₄ (≥95%), LiNH₂ (95%), LiOH (≥98%) and Li₂O (97%, −60 mesh powder) were purchased from Sigma-Aldrich. Solid-state synthesis of LiBH₄∙½NH₃ (s1) was carried out by mechanical milling of LiBH₄, LiNH₂ and LiOH in a molar ratio of 2:1:1, followed by heat treatment (T = 80 °C for 12 hours under Ar atmosphere). Li(BH₄)₀.₂₅(NH₂)₀.₇₅ was synthesized by mechanical milling of LiBH₄ and LiNH₂ in a molar ratio of 1:3, followed by a heat treatment (T = 120 °C for 12 hours under Ar atmosphere). The ball milling procedures producing sample s1 and Li(BH₄)₀.₂₅(NH₂)₀.₇₅ were carried out for 5 min with a 2 min pause for 5 and 59 repetitions, respectively, at a speed of 350 rpm and a ball-to-powder weight ratio of 25:1 using 5 tungsten carbide (WC) balls and a WC vial.

LiBH₄∙NH₃ was synthesized by exposure of LiBH₄ to dry ammonia gas at a pressure of 1 bar for 2 h at T = -10 °C, after which it was dried in vacuo for 1 hour. Synthesis of sample LiBH₄∙½NH₃ (s2) was performed by mechanical milling of LiBH₄, NH₃ and LiBH₄ in 1:1 molar ratio. Sample s3, was synthesized by ball milling a mixture of s1 and Li(BH₄)₀.₂₅(NH₂)₀.₇₅ in mass ratio of 1:3, and sample s4, was synthesized by ball milling a mixture of s1 and Li₂O in mass ratio of 1:4. The mechanical milling procedures producing samples s2, s3 and s4 were carried out for 2 min with a 2 min pause for 5 repetitions at a speed of 200 rpm and a ball-to-powder weight ratio of 15:1 using 3 tungsten carbide (WC) balls and a WC vial.

Powder X-ray Diffraction (PXD) data were collected at room temperature on a Rigaku SMARTLAB diffractometer, equipped with a rotating Cu anode (Cu Kα₁ radiation, 2 kW, λ = 1.5406 Å). The samples were packed in 0.5 mm o.d. capillary tubes in the glove box, sealed with glue, and transferred to the instrument without air exposure. In situ synchrotron radiation powder X-ray diffraction (SR-PXD) data of the LiBH₄∙½NH₃ were collected at the I11 beamline at the Diamond Light Source, England, with λ = 0.825850 Å. The sample was heated up using a heat blower with a ramp rate of 5 °C/min.

Electrochemical impedance spectroscopy (EIS) data were collected on a BioLogic MTZ-35 impedance analyzer equipped with a high-temperature sample holder. Samples were pressed into 6.35 mm diameter pellets of ca. 1 mm thickness under the pressure of 0.63 GPa. All measurements were conducted in an argon atmosphere, and the temperature was measured by a K-type thermocouple 5 mm from the sample. Impedance data were measured at 20 mV ac from 3 MHz to 1 Hz. Ion conductivity data (σ) were derived from Nyquist impedance plots using the x-intercept of the Nyquist semicircle (R), area of the pellet face (A), and pellet thickness (t) according to: σ = t/(R × A). Cyclic voltammetry (CV) was measured using a BioLogic VMP3 multi-channel potentiotstat.

Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) was conducted on a PerkinElmer STA 6000, where 3–5 mg samples were placed in Al₂O₃ crucibles and heated at 5 °C per min under constant argon flow (50 mL·min⁻¹). Simultaneous mass spectrometry (MS) was collected for H₂ (m/z = 2) and NH₃ (m/z = 17), using a Hiden Analytical HPR-20 QMS sampling system. All sample handling was carried out in an Ar-circulated glove box with O₂ < 0.1 ppm and H₂O < 0.1 ppm.
Computational Methods

The migration path for Li\textsuperscript{+} was calculated from first-principles using the Vienna Ab-initio Simulation Package.\textsuperscript{1,2} The calculations were performed within the framework of density functional theory (DFT) employing the generalized-gradient approximation by Perdew, Burke, and Ernzerhof for exchange-correlation functional.\textsuperscript{3} Projector augmented wave potential with a planewave cutoff energy of 600 eV was used.\textsuperscript{4} Li\textsuperscript{+} interstitial is often the major charge carrier in this kind of LiBH\textsubscript{4}-based ionic conductor.\textsuperscript{5-7} Therefore, stable Li\textsuperscript{+} interstitial sites were located using the supercell containing 24 formula units of LiBH\textsubscript{4}·½NH\textsubscript{3} plus one interstitial ion. Then the minimum energy path through some of the most stable sites was obtained by the climbing-image nudged elastic band method\textsuperscript{8} with a supercell of doubled unit cells in the c direction. Only migration along the c direction was considered as the jump distance between the stable sites along the a direction is as large as \(~4.8 \text{ Å} \) (half the lattice parameter a), which would not occur frequently, whereas it is only \(~2 \text{ Å} \) along the c direction.

The bond-valence-based empirical force field calculations have been performed using the program SoftBV.\textsuperscript{9} The ions used for calculations were Li\textsuperscript{+} (mobile ion), B\textsuperscript{3+}, N\textsuperscript{5+}, H\textsuperscript{−}. The minima energy surfaces were drawn using the program Vesta.\textsuperscript{10}
Figure S1. Rietveld refinement of PXD data of s1 measured at room temperature, $\lambda = 0.825850$ Å, showing experimental (blue circles) and calculated (red line) PXD patterns, and a difference plot below (black line). Top tick (LiBH$_4$½NH$_3$, 66.9 wt%), bottom tick (Li$_2$O, 33.1 %). Final discrepancy factors: $R_p = 0.62 \%$, $R_{wp} = 0.93 \%$ (not corrected for background), $R_p = 9.22 \%$, $R_{wp} = 5.86 \%$ (conventional Rietveld $R$-factors), $R_{Bragg}$(LiBH$_4$½NH$_3$) = 3.41 \%, $R_{Bragg}$(Li$_2$O) = 0.319 % and global $\chi^2 = 5.81$. LiBH$_4$½NH$_3$: space group $Pna2_1$, $a = 9.6174(7)$, $b = 13.7476(9)$, $c = 4.4409(5)$ Å; Li$_2$O: space group $Fm-3m$, $a = 4.6195(8)$ Å.

Figure S2. Rietveld refinement of PXD data of LiBH$_4$NH$_3$ measured at room temperature, $\lambda = 1.54056$ Å, showing experimental (blue circles) and calculated (red line) PXD patterns, and a difference plot below (black line). Top tick (LiBH$_4$½NH$_3$, 6.0 wt%), bottom tick (LiBH$_4$NH$_3$, 94.0 %). Final discrepancy factors: $R_p = 4.04 \%$, $R_{wp} = 5.85 \%$ (not corrected for background), $R_p = 30.6 \%$, $R_{wp} = 20.6 \%$ (conventional Rietveld $R$-factors), $R_{Bragg}$(LiBH$_4$½NH$_3$) = 15.8 \%, $R_{Bragg}$(LiBH$_4$NH$_3$) = 7.70 % and global $\chi^2 = 10$. LiBH$_4$½NH$_3$: space group $Pna2_1$, $a = 9.6178(1)$, $b = 13.7480(2)$ Å, $c = 4.44104(5)$ Å; LiBH$_4$NH$_3$: space group $Pnma$, $a = 5.9994(8)$, $b = 4.4854(8)$, $c = 14.4162(4)$ Å.
Figure S3. Rietveld refinement of PXD data of s2 measured at room temperature, $\lambda = 1.54056$ Å, showing experimental (blue circles) and calculated (red line) PXD patterns, and a difference plot below (black line). Top tick (LiBH$_4$·½NH$_3$, 94.8 wt%), bottom tick (LiBH$_4$, 5.2 %). Final discrepancy factors: $R_p = 3.45 \%$, $R_w$ = 4.53 % (not corrected for background), $R_p = 28.3 \%$, $R_w$ = 17.7 % (conventional Rietveld $R$-factors), $R_{Bragg}$(LiBH$_4$·½NH$_3$) = 6.01 %, $R_{Bragg}$(LiBH$_4$) = 12.6 % and global $\chi^2 = 1.15$. LiBH$_4$·½NH$_3$: space group Pna2$_1$, $a = 9.6178(1)$, $b = 13.7480(2)$ Å, $c = 4.44104(5)$ Å; LiBH$_4$: space group Pnma, $a = 7.141$, $b = 4.431$, $c = 6.748$ Å.

**Figure S8.** Conduction pathway for Li$^+$ in LiBH$_4$½NH$_3$ calculated by the program SoftBV and drawn by Vesta. Li atom is shown in blue, and B is in green, N is in orange and H is in grey. Ribbons represent the conduction paths within a-c layers along the c-axis. The surface seen is the minimum energy surface (green and blue are 2 sides of the surface).

**Figure S9.** Energy barriers of Li$^+$ ion migration pathway along the c-axis in the interlayers in the a-c plane of the LiBH$_4$½NH$_3$ unit cell, calculated by the program SoftBV using Bond Valence approach. The energy barriers of the 1D pathways is calculated to be ~ 1 eV, which is higher than what DFT proposed (0.16 eV). As SoftBV does not take into account the dynamics of NH$_3$, the low energy barriers observed and calculated by DFT are due to NH$_3$ mediation.
Figure S10. CV curves of LiBH$_4$:½NH$_3$: (A) from OCV to 0 V, (B) from OCV to 2.5V and (C) from -0.1 to 3V, using linear sweep voltammetry on a stainless-steel working electrode. Scanning rate: 1 mV s$^{-1}$, temperature: 25 °C.

**Thermodynamic consideration of formation of LiBH_4½NH_3**

Reaction scheme eq. 1, may be considered as consisting of two reaction steps:

eq.1a: LiNH_2 + LiOH → Li_2O + NH_3

eq.1b: 2LiBH_4 + NH_3 → 2LiBH_4½NH_3

We do not have thermodynamic data of LiNH_2 and LiBH_4½NH_3, and cannot do a quantitative thermodynamic calculation, however, qualitatively we do not expect any significant change in entropy, as no gas is released. Thus, the reaction is likely driven by the reaction enthalpy. This is supported by the very exothermic reaction between most metal borohydrides and ammonia, e.g. observed for the reaction between NH_3 and LiBH_4, Mg(BH_4)_2, Ca(BH_4)_2, Y(BH_4)_3, etc.
