Comparison of the catalytic turnover frequency (TOF) between complexes $\mathbf{2}$ and $\mathbf{3}$ in the presence of $\mathrm{CF}_{3} \mathrm{COOH}$.

As shown in Fig. 3, the catalytic peak current ( $\mathrm{i}_{\text {cat }}$ ) increased almost linearly with acid concentration, indicating that at fixed catalyst concentration the reaction is first order with respect to acid concentration. Thus, the catalytic turnover frequency (TOF) of complexes 2-4 can be calculated by the following equation ${ }^{[1]}$ :

$$
\frac{i_{\text {cat }}}{i_{\mathrm{p}}}=\frac{n}{0.446} \sqrt{\frac{R T k_{\mathrm{obs}}}{F v}}
$$

where $i_{\text {cat }}$ is the peak current in presence of acid, $i_{p}$ is the peak current in the absence of acid, n is the number of electrons involved in the catalytic process, $\mathrm{k}_{\mathrm{obs}}$ (turn over frequency, TOF) is the observed rate constant, R is ideal gas constant, T is temperature in Kelvin (298 K), F is Faraday's constant, and $v$ is the scanning rate. According to this equation, the values of TOF for complexes 2-4 with different equivalent of $\mathrm{CF}_{3} \mathrm{COOH}$ can be calculated and showed in Fig. S3.
