SUPPORTING INFORMATION

Materials and methods

Ethidium bromide (EB), Serum albumins (BSA/HSA), Calf Thymus DNA (CT-DNA) were purchased from HiMedia and used as received. Melting points were measured in a Lab India apparatus. Infrared (IR) spectra were measured on a JASCO FT-IR 4100 instrument as KBr pellets between 400–4000 cm⁻¹. The electronic spectra of the compounds were recorded in dichloromethane using a Spectrophotometer (JASCO V-630) in the 200–800 nm range. Emission spectra were recorded by using JASCO FP 6600 Spectrofluorimeter. ¹H NMR spectra were recorded in DMSO at room temperature with a Bruker 400 MHz instrument chemical shift relative to tetramethylsilane (TMS).

X-ray Crystallography

Hydrogen bonding in complexes 1–4

In the tetrameric crystal structure of **1**, each monomeric unit showed three hydrogen bonds: The hydrogen atom of H(3A) of amino group N(3)–H(3A) is engaged in intermolecular hydrogen bonding with oxygen atom O(1B) of the DMF molecule, which came from solvent of crystallisation (O(1B)–N(3A)=3.15(4)). The hydrogen atom H(3B) of amino group N(3)–H(3B) is involved in intermolecular hydrogen bonding with ring carbonyl oxygen atom O(2) of a second molecule and the ring carbonyl oxygen atom O(2) of the first molecule involved in hydrogen bond with hydrogen atom H(3B) of the amino group of the another molecule. This intermolecular hydrogen bonding leads to an unremitting 3D chain formation (Fig. S13) at four ends of the tetramer with a distance of 2.971(8) Å [O(2)–N(3)=2.971(8); N(3)–H(3B)⋯O(2) = 172.00(8)°] (Table S3).

In complex **2**, the molecular packing suggests that the stabilization of the lattice may be due to eight intermolecular hydrogen bonds, each monomeric unit involving the two hydrogen bonds: one hydrogen bond between the ring carbonyl oxygen atom O(2) of the first molecule and hydrogen (H3) atom of the terminal N(3)–H(3) group of the second molecule and second hydrogen bond involves the hydrogen (H3) atom of the terminal N(3)–H(3) group of the first molecule and ring carbonyl oxygen atom O(2) of the another molecule (N(3)–O(2), O(2)–N(3) is 2.895 Å). All the eight intermolecular hydrogen bondings led to give a 3D layer structure to the complex **2** (Fig. S14).

The presence of four intermolecular hydrogen bondings in complex **3** creates a 2D network (Fig. S15; Table S3). In tetrameric unit of complex **3**, one of the monomeric unit involved in intermolecular hydrogen bonding with carbonyl oxygen atom O(2) and the hydrogen atom H(12) of terminal N(12)–H(12) group of second molecule and the hydrogen atom H(12) of terminal N(12)–H(12) group in same monomeric unit engaged in intermolecular hydrogen bonding with carbonyl atom O(2) of the another molecule. The hydrogen atom H(12) of terminal N(12)–H(12) group in second monomeric unit is involved in intermolecular hydrogen bonding with carbonyl oxygen atom O(2) of a second molecule. Third monomeric unit involving the hydrogen bond between the ring carbonyl oxygen atom O(2) and hydrogen (H3) atom of the terminal N(3)–H(3) group of the second molecule. In complex **4**, an intermolecular hydrogen bonding was found between the terminal nitrogen and the oxygen atom of the DMF [N(3)...O(3) (2.858 Å); N(3)–H(3)···O(3)=174.56 °] which came through the solvent of crystallization (Fig. S16; Table S3).
