Synthesis of the tris-benzimidazole ligands and their precursors

The first step towards the synthesis of the tris-benzimidazole ligands is a nucleophilic aromatic substitution (S_NAr) reaction, in which an excess of a commercially available substituted *ortho*-halogenated nitrobenzene is reacted with tris(2-aminoethyl)amine. The core prerequisite of a S_NAr reaction is that a strong electron-withdrawing group is present in either the *ortho*- or *para*- positions, relative to the potential leaving group, which serves to stabilize the Meisenheimer complex formed as the reaction proceeds. The desired compounds were isolated and purified *via* column chromatography to yield either bright yellow solids (1 and 2) or a dark orange solid (3) in moderate yields (35 – 48%) and are soluble in several polar organic solvents including ethanol, methanol, acetone and dimethylsulfoxide. The ¹H NMR spectra of the tris-nitrobenzene compounds 1 – 3 reveals the presence of a triplet at 8.1 – 8.5 ppm corresponding to the secondary amine protons which supports complete substitution of all three arms of the tris-core. Furthermore, the splitting pattern observed in the aromatic regions of the spectra (6.5 – 8.0 ppm) is consistent with a splitting pattern associated with a 1,2,4-trisubstituted aromatic ring with three electronically discrete functional groups. The only difference is compound 1, as 1 consists of a 1,2-disubstituted aromatic ring.

The synthesis of the tris-1,2-benzenediamines from the tris-nitrobenzenes (1 - 3) involves the reduction of the nitro- functionalities to primary amine functionalities. This was achieved by using zinc and ammonium chloride as reducing agents under mild conditions. This reduction proved to be highly efficient affording the tris-1,2-diamines in excellent yields (75 – 97%).

The comparison of each ¹H NMR spectrum of the tris-1,2-diamines (4 - 6) with the corresponding trisnitrobenzene (1-3) results in two main observations. Firstly, the signal between 4.3 - 3.8 ppm in each spectrum which corresponds to the protons of the primary amine functionalities is the first indicator of successful reduction of the nitro-functionalities to primary amine groups. Secondly, the aromatic signals of 4 - 6 converge and some coalesce relative to the aromatic signals of the corresponding nitro-benzenes (1 - 3), attesting to the similar electronic effects of the primary and secondary amine groups on the aromatic ring which corroborates successful reduction. Further analysis of the tris-1,2-diamines (4-6) using infrared (IR) spectrometry revealed two absorption bands between 3299 and 3376 cm⁻¹. These correspond to the symmetrical and asymmetrical stretches of the N-H bonds of the primary amine moieties and are thus indicative of the successful reduction of the nitro- groups to primary aryl amine groups.

Finally, the synthesis of the tris-benzimidazole ligands, from the tris-1,2-benzenediamines (4 - 6) entailed a cyclisation-condensation reaction with either benzaldehyde or 2-pyridinecarboxaldehyde in the presence of a catalytic amount of trifluoroacetic acid and magnesium sulfate.
