## Thermogravimetric Analyses.

As shown in Figure S7, the thermal stability of compounds $\mathbf{1}$ and $\mathbf{2}$ have been determined by using thermogravimetric analyses. The thermogravimetric curves are very similar and show two major weight loss stages in the region of 50$825^{\circ} \mathrm{C}$. Hence, only the thermogravimetric curve of $\mathbf{1}$ is taken as a representative to describe in detail. For $\mathbf{1}$, the observed total weight loss ( $15.46 \%$ ) is agreement with the calculated value ( $15.35 \%$ ). The first weight loss of 4.96 $\%$ from 50 to $300^{\circ} \mathrm{C}$ was due to the release of twenty-eight lattice water molecules and six coordinated water ligands (calcd $4.87 \%$ ). The last weight loss of $10.50 \%$ from 300 to $825^{\circ} \mathrm{C}$ was corresponded to the removal of two $\mathrm{As}_{2} \mathrm{O}_{3}$ molecules and twelve ligands (calcd $10.48 \%$ ). The first weight loss is more than the theoretical value, which may be ascribed to the fact that the samples have been weathered before the thermogravimetric analyses. The similar process of thermogravimetric analyses of compound $\mathbf{2}$ is shown in Table S6.
