## Experimental procedures

### General

IR spectra were recorded on a Shimadzu IRSpirit-T spectrometer equipped with an ATR accessory. NMR spectra were recorded on Bruker DRX-400 ( $^1\text{H}$ , 400 MHz;  $^{19}\text{F}$ , 376 MHz), Bruker Avance-400 ( $^1\text{H}$ , 400 MHz;  $^{19}\text{F}$ , 376 MHz;  $^{13}\text{C}$ , 101 MHz) and Bruker Avance III-500 ( $^1\text{H}$ , 500 MHz;  $^{19}\text{F}$ , 471 MHz  $^{13}\text{C}$ , 126 MHz) spectrometers in DMSO-*d*<sub>6</sub> or CDCl<sub>3</sub>. The chemical shifts ( $\delta$ ) are reported in ppm relative to the internal standard TMS ( $^1\text{H}$  NMR), C<sub>6</sub>F<sub>6</sub> ( $^{19}\text{F}$  NMR) and to residual signals of the solvents ( $^{13}\text{C}$  NMR). 2D  $^1\text{H}$ - $^1\text{H}$  NOESY spectrum was acquired on a Bruker Avance-400 spectrometer with 0.3 s mixing time. The HRMS spectra were obtained using the UHR-QqTOF maXis Impact HD (Bruker Daltonics) mass spectrometer. Elemental analysis was performed on a PerkinElmer PE 2400 automatic analyzer. Melting points were determined on an SMP40 apparatus. The starting 3-nitro-2*H*-chromenes **4a–k** were prepared according to described procedures.<sup>1</sup> For the study of antitumor activity, the human cervical carcinoma cells HeLa, obtained from the Bank of Cell Cultures of the Institute of Cytology of the Russian Academy of Sciences, St.-Petersburg, Russia, was used.

### General procedure for synthesis of spiro[chromenopyrrolidine-oxindoles] **5**, **6** and **7**

Method A: A mixture of the corresponding nitrochromene **4** (1.0 mmol), isatin **1** (1.0 mmol) and sarcosine (0.13 g, 1.5 mmol) was stirred in 2-propanol (4 mL) at 55–60 °C for 3.5–9 h (see table 1) and the reaction progress was monitored by TLC. Upon completion, the mixture was filtered off. Water (1.5 mL) was added to the filtrate, and the precipitate was filtered off. Combined precipitates were washed with water and dried on air. In some cases, additional recrystallisation from the mixture 2-propanol–H<sub>2</sub>O (80:20) was necessary.

Method B: A mixture of the corresponding nitrochromene **4** (1.0 mmol), isatin **1** (1.0 mmol) and sarcosine (0.13 g, 1.5 mmol) was refluxed in 1,4-dioxane (8 mL) for 48 or 72 h (see Table 1). After that, the mixture was concentrated under reduced pressure and the residue was purified by column chromatography on silica gel (elution with chloroform). After removal of the solvents under reduced pressure, the solid formed was recrystallized from hexane–dichloromethane (2:1).

### Assessment of *in vitro* cytotoxic activity of compounds **5** and **6**

The cells were seeded into 96-well microplates in a seeding dose of  $2 \times 10^5$  cells/mL and cultured for 24 h in the DMME medium with glutamine (1%) in the presence of 10% fetal calf serum and gentamicin (50 mg/L) at 37 °C in a humidified atmosphere with 5% v/v CO<sub>2</sub>. Then the tested compounds **5** and **6** were added to the wells in various concentrations ( $10^{-7}$  M,  $10^{-6}$  M,  $10^{-5}$  M,  $10^{-4}$  M). Cells with compounds were incubated for 48 h, after which cell viability was assessed using the standard MTT test,<sup>2</sup> based on

the reduction of the yellow tetrazole salt by living cell mitochondrial dehydrogenases to formazan crystals, soluble in DMSO. Experiments were performed in 3 replicates, with negative (culture medium), positive ( $10^{-3}$  M solution of hydrogen peroxide in phosphate buffer solution) controls and solvent control (DMSO). The results of the MTT test were evaluated by comparing the optical density of the formazan solution measured on a flatbed scanner ELx800 (BioTek, USA) at a wavelength of 570 nm in the experimental and control wells and the cytotoxicity index (IC) was calculated. The cytotoxicity index was determined for each concentration of the studied substances. Using probit-regression, the IC<sub>50</sub> score (the concentration of the substance that is required for 50% inhibition of cell survival) was calculated. The parameters of the arithmetic mean value and the standard error were calculated. The differences in the average values according to the Mann-Whitney test with  $p < 0.05$  were considered reliable. For the statistical analysis Microsoft Excel and Statistica 2009 were used.

### X-ray crystallography

Crystals of **5a**, **6l** and **8e** were grown by the slow evaporation of an acetonitrile solution. Diffraction data were collected on a Xcalibur Eos (compound **5a**) or on an Xcalibur 3 (compounds **6l** and **7e**) automatic diffractometer using the standard procedure (Mo-K $\alpha$  radiation ( $\lambda$  = 0.71073 Å) or Cu-K $\alpha$  radiation ( $\lambda$  = 1.54184 Å), graphite monochromator,  $\omega$ -scanning, 295(2) K). An empirical adjustment for absorption was introduced. The structures were solved by direct methods and refined by the full-matrix least-squares method using the SHELX-97 program package.<sup>4</sup> All non-hydrogen atoms were refined with anisotropic atomic displacement and hydrogen atoms were included at the calculated positions using a riding model. The geometrical parameters were analysed using the programs OLEX2.<sup>5</sup>
