1 **Calculations:**

2 (1) The specific capacitances ( $C_g$ ) of the N-GNTs@NSNs on GS electrode calculated  
3 from GCD curves are obtained according to the following equation:

4 
$$C_g = \frac{I\Delta t}{m\Delta V}$$

5 where  $I$  is the discharge current,  $\Delta t$  is the discharge time in GV test,  $m$  is the mass  
6 loading of the electrode materials,  $s$  is the area of the electrode materials, and  $\Delta V$  is  
7 the voltage window.

8 (2) The specific capacitance ( $C_{\text{device}}$ ) of the N-GNTs@NSNs on GS// AC on NF  
9 asymmetric supercapacitor (ASC) device can be obtained in accordance with the  
10 following equation:

11 
$$C_{\text{device}} = \frac{I\Delta t}{M\Delta V}$$

12 Herein,  $I$  is the discharge current,  $\Delta t$  is the discharge time in GCD test,  $M$  is the mass  
13 of the device, and  $\Delta V$  is the voltage window of the device.

14 (3) Methods to calculate the energy and power density of the ASC device:

15 
$$E = \frac{1}{7.2} C_{\text{device}} \Delta V^2; P = \frac{E}{t}$$

16 Here,  $C_{\text{device}}$  is the specific capacitance of the device,  $\Delta V$  is the potential window, and  
17  $t$  is the discharge time.

18 (4) The measured potentials are referred to RHE using the following equation:

19 
$$E(\text{RHE}) = E(\text{SCE}) + 0.059\text{PH} + 0.241$$

20 (5) The electrochemical double-layer capacitance ( $C_{\text{dl}}$ ) is determined from the CV  
21 curves measured in a potential range without redox process by following equation:  
22

1 
$$Cdl = \frac{I}{\nu}$$

2 where  $I$  is the charging current ( $\text{mA cm}^{-2}$ ), and  $\nu$  is the scan rate ( $\text{mV s}^{-1}$ ).
