## 1. Experimental Section

## General information

All of the reagents are analytically sourced from commercial reagent companies and do not require further purification for direct use. The water used in the laboratory comes from the Milli-Q reference system. Thin-layer chromatography (TLC) and silica gel for column chromatography comes from Qingdao Marine chemical plant (200-300 mesh). The spectra of chemiluminescent and fluorescence were analyzed using Molecular Devices SpectraMax M5. Spectrometer. NMR spectra were obtained on an Bruker Avance 400 MHz , Bruker Avance 600 MHz apparatus. 96 -well black plate imaging was used with Bio-rad Biorad Gel Doc XR. Cell imaging was performed using Axio Observer D1.

## Cell culture and fluorescence imaging

Adenocarcinoma of human alveolar basal epithelial cells ( HeLa cells) were cultured in DMEM high glucose media supplemented with $10 \%$ fetal bovineserum, $1 \%$ Penstrep, $0.2 \%$ Amphotericin B. The cells were grown overnight at $37^{\circ} \mathrm{C}$ incubator with $5 \% \mathrm{CO}_{2}$. HeLa were seeded at a density of $0.3 \times 106$ cells in 35 mm dish and kept overnight prior to cell imaging studies.

## 3. Supporting Figures

The detection limit was calculated based on the fluorescence titration. To determine the $\mathrm{S} / \mathrm{N}$ ratio, the emission intensity of $\mathbf{C L}-\mathbf{H Z}$ without hydrazine was measured by 11 times and the standard deviation of blank measurements was determined. The detection limit (DL) of CL-HZ for hydrazine was determined from the following equation: $\mathrm{DL}=3 \sigma / \mathrm{k}, \sigma$ is the standard deviation of the blank solution; $k$ is the slope of the calibration curve. From the graph we get slope $=3.634 \times 10^{8}$, and $\sigma$ value is 113.2 Thus using the formula we get the Detection Limit $=9.345 \times 10^{-7} \mathrm{M}$
