### Z-scan data fit formulae:

Open aperture transmittance:

$$T_{\text{noA}} = \frac{1}{\left[ 1 + (n-1)\alpha_n L' \left[ \frac{I_0}{\left(1 + \frac{z}{z_0}\right)^2} \right]^{(n-1)} \right]^{\frac{1}{(n-1)}}} \quad \text{Eqn. 1}$$

Where  $n = 1, 2, \dots, n$ ;  $\alpha_n = n$  photon absorption co-efficient; Effective length,  
 $I_0 =$  input peak intensity;  $z_0 =$  Rayleigh range at wavelength  $\lambda$  (nm).

$$L' = 1 - \frac{e^{-(n-1)\alpha_n L}}{(n-1)\alpha_n}$$

Closed aperture transmittance:

$$T_{\text{CA}} = 1 \pm \frac{4\Delta\phi \left(\frac{z}{z_0}\right)}{\left[\left(\frac{z}{z_0}\right)^2 + 9\right] \left[\left(\frac{z}{z_0}\right)^2 + 1\right]} \quad \text{Eqn. 2}$$

$\Delta\phi$  is obtained from fitted curve and then nonlinear refractive index  $n_2$  is calculated as:

$$n_2 = \frac{\Delta\phi\lambda}{2\pi L' I_0} \quad \text{Eqn. 3}$$

The third order non linear susceptibility,  $\chi^{(3)} = [(\chi_R^{(3)})^2 + (\chi_I^{(3)})^2]^{1/2}$

$$\chi_R^{(3)} = 2cn_0^2 \varepsilon_0 n_2 \quad \text{Eqn. 4}$$

$$\chi_I^{(3)} = \frac{c^2 \varepsilon_0 n_0^2 \alpha_2}{\omega}$$

Where,  $c = 3 \times 10^8$  m/s;  $\varepsilon_0 =$  absolute permittivity;  $\omega =$  frequency of laser radiation. The n-photon absorption cross-sections are calculated as:

$$\sigma_n = \frac{(\hbar\omega)^{n-1}}{N} \alpha_n \quad \text{Eqn. 5}$$

$N =$  solute molecule concentration.

**Example:** For **800 nm**, the average power used was 0.4 mW with beam radius of 1 mm and focusing lens of 10 cm focal length. Thus, the Rayleigh range,  $Z_0$  was calculated to be 2.54 mm.

Effective length,  $L' = \frac{1 - e^{-0.354}}{0.354} \text{ cm} = 0.084$

Peak intensity,

$$I_0 = \frac{0.4 \times 10^{-3}}{\pi \times (0.0025)^2 \times 70 \times 10^{-15} \times 10^3} \frac{\text{W}}{\text{cm}^2} = 2.8 \times 10^{11} \text{ W/cm}^2$$

For 800 nm, we observe two-photon absorption hence,  $n = 2$ . Putting above parameters in Eqn. 1, we fit it with experimental open aperture z-scan data to obtain NLO absorption coefficient,  $\alpha_2$  to be  $12.0 \times 10^{-11}$  cm/W. Similarly, from Eqn. 2, we can obtain the value of  $\Delta\Phi$  which was obtained to be 0.17. Putting this value to Eqn. 3, the nonlinear refractive index obtained was:

$$n_2 = \frac{0.17 \times 8 \times 10^{-5}}{2\pi \times 0.084 \times 2.8 \times 10^{11}} = 0.92 \times 10^{-16} \text{ cm}^2/\text{W}$$

Using Equation 4 the value of NLO susceptibilities were calculated and tabulated in Table 2.

The two-photon absorption cross-section was calculated using equation 5 where no. of molecules in 0.07 mM of sample is given by,

$$N = 0.07 \times 10^{-3} \times 6.02 \times 10^{23} = 4.21 \times 10^{19} \text{ Molecules.}$$

Thus, 2PA cross-section was calculated as,

$$\sigma_2 = \frac{6.62 \times 10^{-34} \times 3 \times 10^8 \times 12 \times 10^{-11}}{8 \times 10^{-7} \times 4.21 \times 10^{14} \times 10^{-3}} = 7.08 \times 10^{-47} \text{ cm}^4 \text{ s photon}^{-1} \text{ molecule}^{-1}$$

$$= 7080 \text{ GM}$$

$$1 \text{ GM} = 10^{-50} \text{ cm}^4 \text{ s photon}^{-1} \text{ molecule}^{-1}$$

For  $\lambda = 1000$  nm, the average power taken was 0.75 mW with Rayleigh range of 3.18 mm. This effective length calculated was 0.072 cm. Rest of the parameters were same as  $\lambda = 800$  nm.

Peak intensity,

$$I_0 = \frac{0.75 \times 10^{-3}}{2\pi \times 70 \times 10^{-15} \times 10^3 \times \pi \times (0.0038)^2} = 3.36 \times 10^{11} \text{ W/cm}^2$$

For 1000 nm, we observe three-photon absorption hence,  $n = 3$ . Putting above parameters in Eqn. 1, we fit it with experimental open aperture z-scan data to obtain NLO absorption coefficient,  $\alpha_3$  to be  $2.7 \times 10^{-21}$  cm<sup>3</sup>/W<sup>2</sup>. Similarly, from Eqn. 2, we can obtain the value of  $\Delta\Phi$  which was obtained to be 2.8. Putting this value to Eqn. 3, the nonlinear refractive index obtained was:

$$n_2 = \frac{2.8 \times 10^{-4}}{2\pi \times 3.36 \times 10^{11} \times 0.072} = 18.4 \times 10^{-16} \text{ cm}^2/\text{W}$$

The three-photon cross section obtained using equation 5 was,

$$\sigma_2 = \frac{(6.62 \times 10^{-34} \times 3 \times 10^8)^2 \times 2.7 \times 10^{-21}}{(10^{-6})^2 \times 4.21 \times 10^{19}} \text{ cm}^6 \text{ s}^2$$

$$= 2.53 \times 10^{-78} \text{ cm}^6 \text{ s}^2$$

For  $\lambda = 1500$  nm, the average power taken was 0.7 mW with Rayleigh range of 4.7 mm. This effective length calculated was 0.08 cm. Rest of the parameters were same as  $\lambda = 800$  nm.

Peak intensity,

$$I_0 = \frac{0.75 \times 10^{-3}}{\pi \times (0.0047)^2 \times 70 \times 10^{-15} \times 10^3} = 1.4 \times 10^{11} \text{ W/cm}^2$$

For 1500 nm, we observe four-photon absorption hence,  $n = 4$ . Putting above parameters in Eqn. 1, we fit it with experimental open aperture z-scan data to obtain NLO absorption coefficient,  $\alpha_4$  to be  $2.2 \times 10^{-32} \text{ cm}^5/\text{W}^3$ . Similarly, from Eqn. 2, we can obtain the value of  $\Delta\Phi$  which was obtained to be 1.35. Putting this value to Eqn. 3, the nonlinear refractive index obtained was:

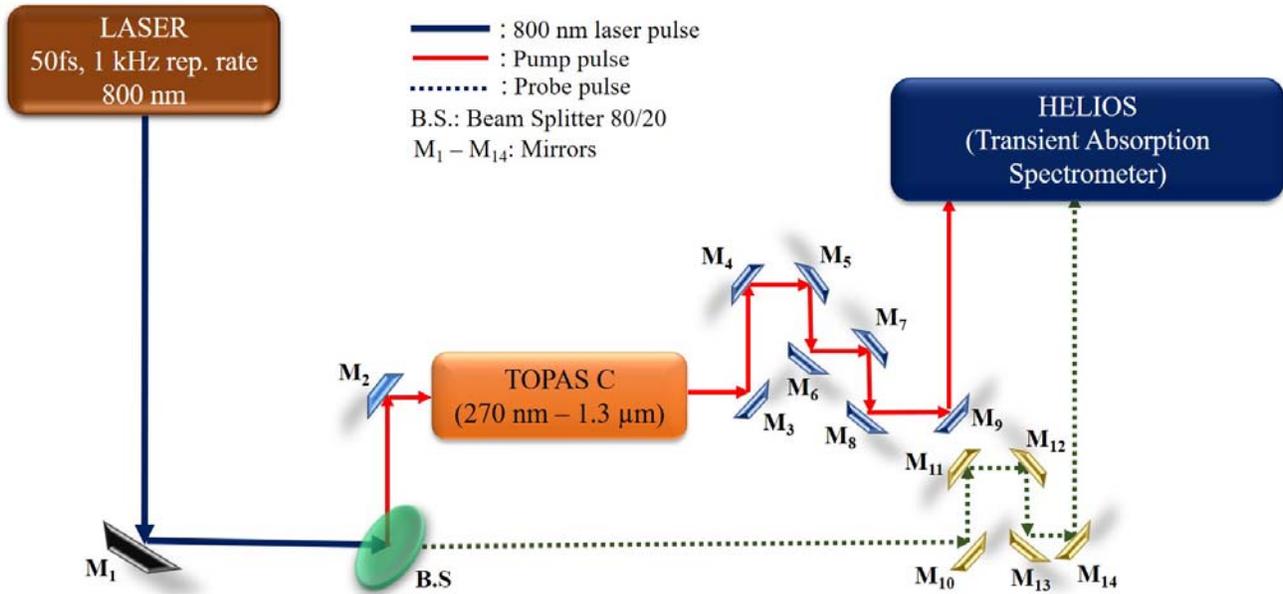

$$n_2 = \frac{1.35 \times 1500 \times 10^{-7}}{2\pi \times 0.08 \times 1.4 \times 10^{11}} = 28.9 \times 10^{-16} \text{ cm}^2/\text{W}$$

The four-photon cross section obtained using equation 5 was,

$$\sigma_2 = \left( \frac{6.62 \times 10^{-34} \times 3 \times 10^8}{1500 \times 10^{-9}} \right)^3 \times \left( \frac{2.2 \times 10^{-32}}{4.21 \times 10^{19}} \right) \text{ cm}^8/\text{s}^3$$

$$= 12.13 \times 10^{-108}$$

### Femtosecond Transient Absorption Spectroscopy experimental schematic:

**Figure S11.** Schematic of the fs-TAS setup used for photophysical studies of PBIPC at ACRHEM, University of Hyderabad, India.

**Table S3.** Decay lifetimes of relaxation dynamics in PBIPC for different wavelengths.

<b>Excitation wavelength</b>	<b>Peak maxima</b>	<b><math>\tau_R</math> (ps)</b>	<b><math>\tau_1</math> (ps), <math>\tau_2</math> (ps)</b>	<b><math>\tau_3</math> (ps)</b>
400 nm	532 nm	0.131	5.59, 333.9	1300
	640 nm	0.123	21.02	346
	700 nm	0.241	8.60	1286
650 nm	532 nm	1.36	8, 216.3	1403
	640 nm	1.39	3.62	408
	698 nm	1.32	142	1340

$\tau_R$ : Rise time;  $\tau_1 / \tau_2$ : shorter decay component showing IC and/ or VC;  $\tau_3$ : longer decay component showing ISC. Error involved is  $\pm 10\%$ .
