Figure S1. The free energy profiles along the hydride transfer step by path B.

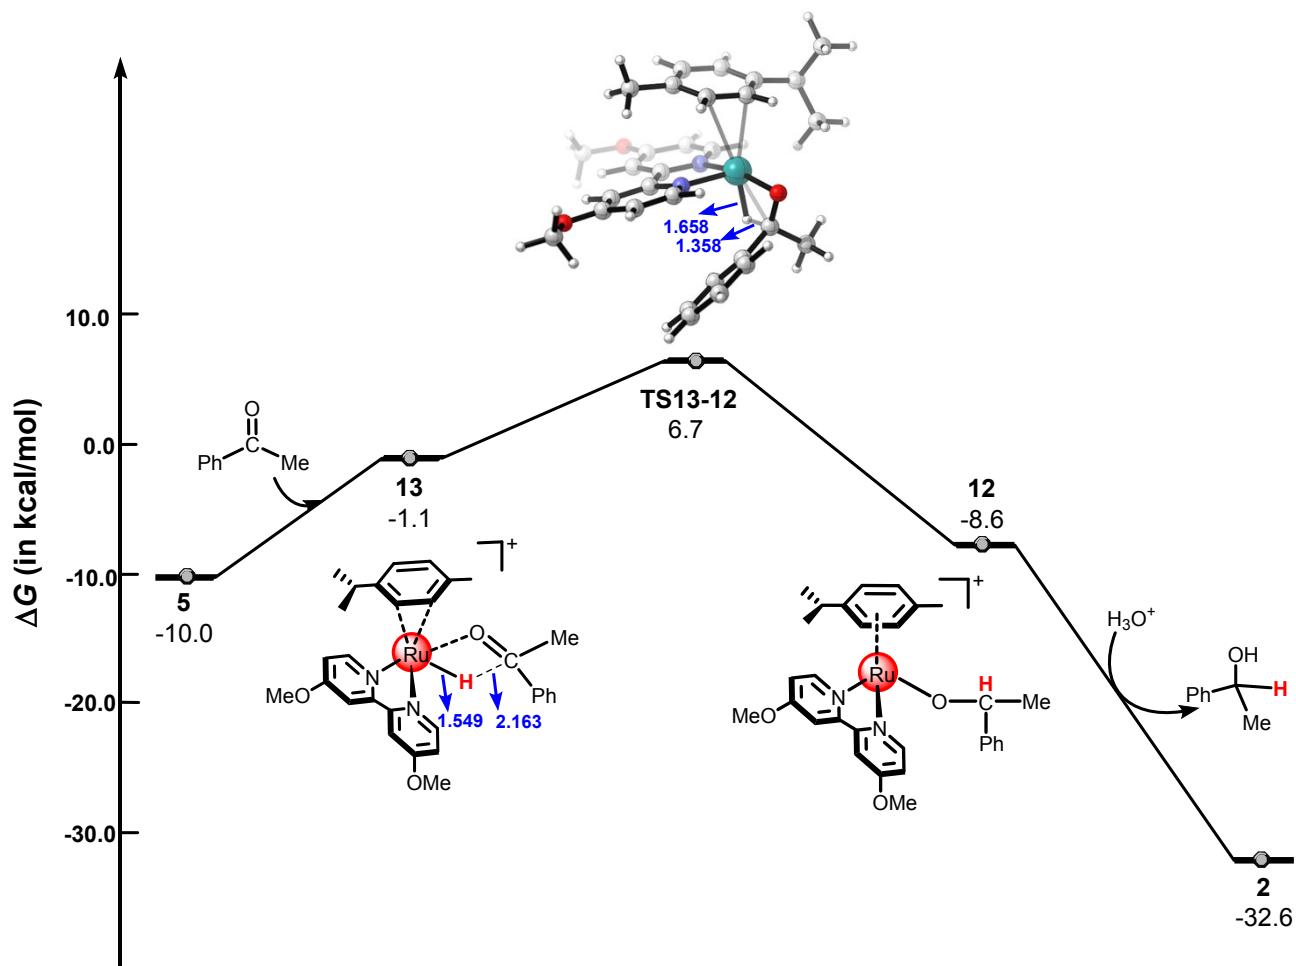

Path B: In this pathway, the ketone substrate could be stabilized with formic acid through hydrogen bond. Firstly, the ketone stabilized with formic acid coordinates with metal hydride **5** to form intermediate **9**. Then the hydride is transferred from Ru center to the carbon atom of ketone via **TS9-10** with an energy barrier of 12.5 kcal/mol. Subsequently, intermediate **10** is formed, the free energy of complex **10** is -18.3 kcal/mol. The free energy profiles along path B are shown in Figure S1, in this pathway, the energy barrier is 12.5 kcal/mol from **9** to **TS9-10**. As a result, we can conclude that path B is less favorable than path A.

Figure S2. The free energy profiles along the hydride transfer step by path C.

Path C: In this pathway, the ketone substrate is coordinated to the Ru atom during the hydride transfer by inner-sphere mechanism. As shown in Figure S2, the oxygen atom of acetophenone forms the Ru-O bond with Ru center of complex **5** firstly, resulting in the dissociation of one 4-methylpyridine to form complex **11** with a high energy barrier of 22.5 kcal/mol. Subsequently, the hydride transfers to carbon atom of ketone through **TS11-12**, which owing an energy barrier of 5.3 kcal/mol. From **11** to **TS11-12**, the C-H distance decreases from 2.990 Å to 1.104 Å, indicating that the C-H bond is formed. Path C has an energy barrier of 27.8 kcal/mol, which is 22.9 kcal/mol higher than that of Path A. As a result, we can conclude that path C is less favorable than path A.

Figure S3. The free energy profiles along the hydride transfer step by path D.

Path D: In this pathway, the ketone substrate also coordinates to the Ru atom during the hydride transfer by inner-sphere mechanism. Meanwhile, the arene ring occurs the ring slippage from η^6 -coordination to η^2 -coordination to form complex **13**. Then the hydride transfer to the carbon atom of ketone through **TS13-12**, which owing an energy barrier of 16.7 kcal/mol (see Figure S3). Obviously, Path A is more favorable than Path D.

Figure S4. The free energy profiles of hydrogen release pathway when hydrated proton is H_7O_3^+ .

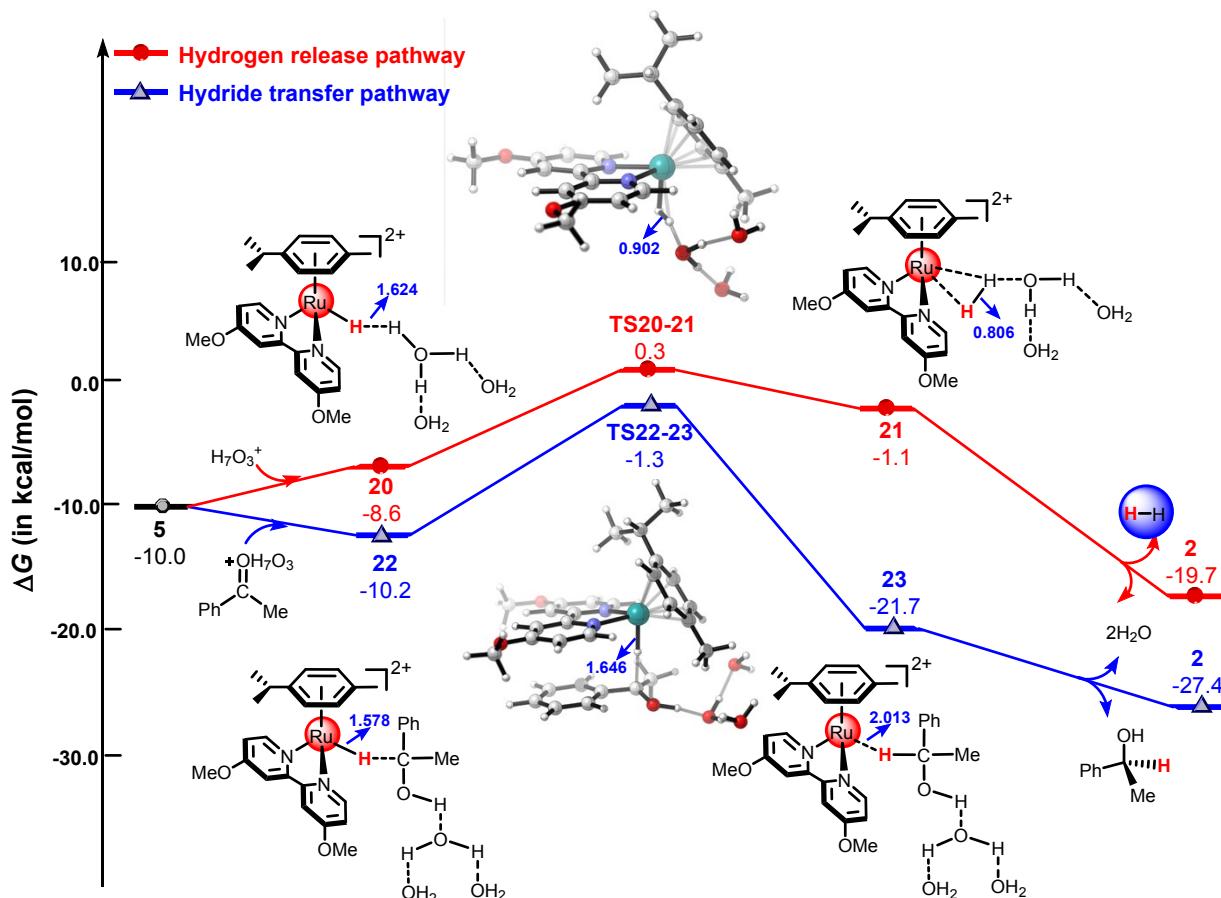

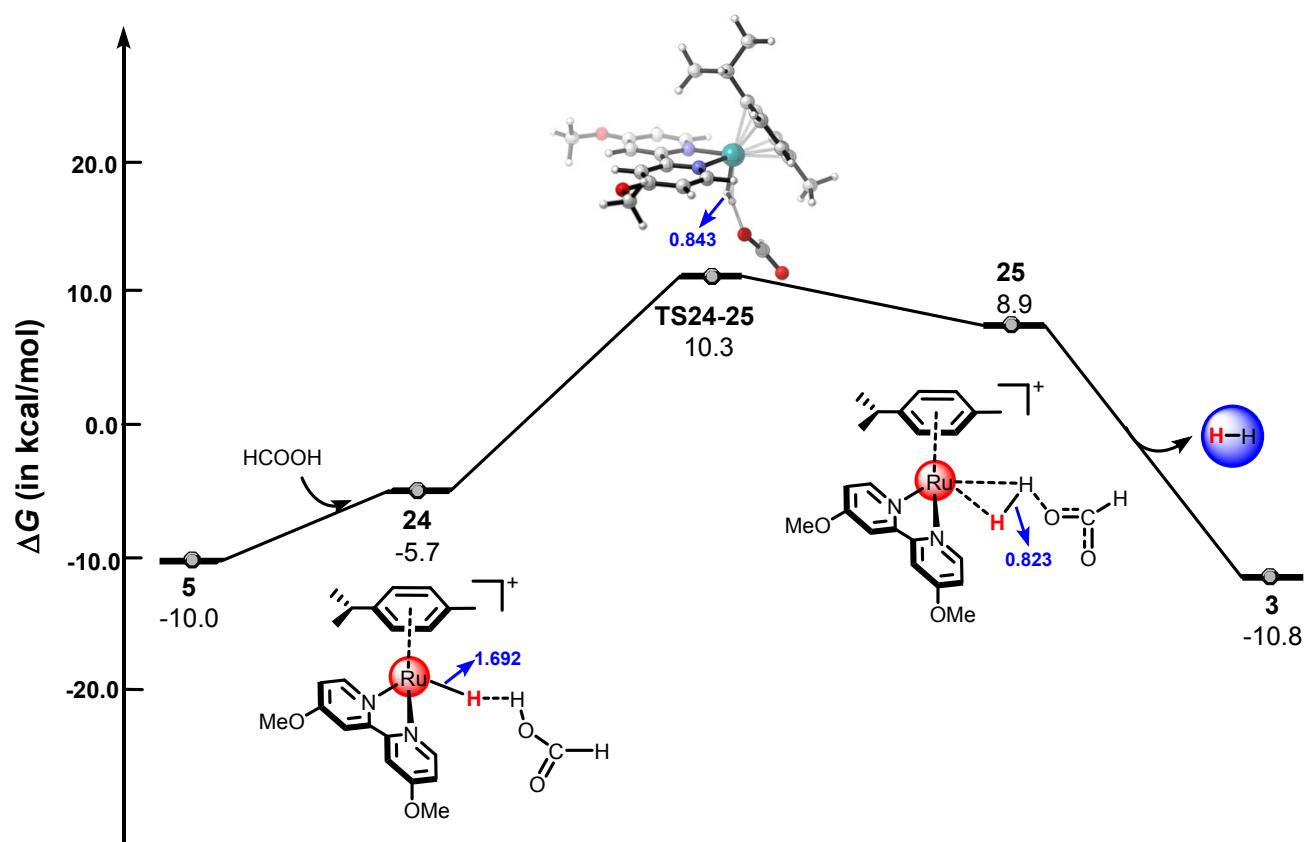

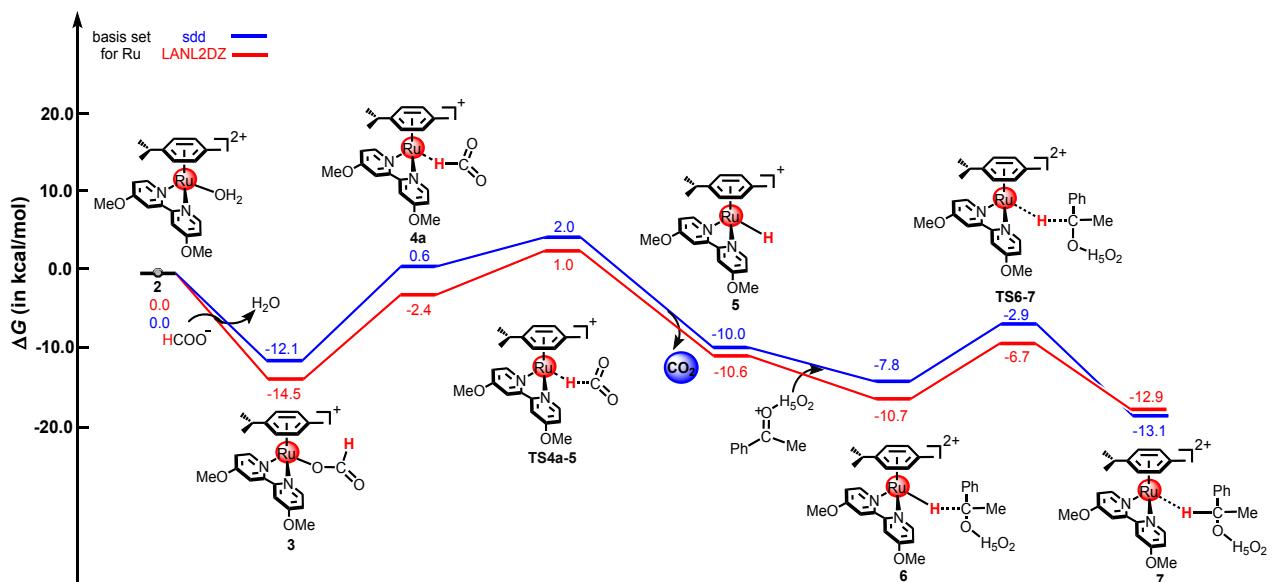

Figure S4 shows the free energy profiles of dihydrogen release pathway and hydride transfer pathway mediated by H_7O_3^+ , the energy barrier of the dihydrogen release pathway is 10.3 kcal/mol. Interestingly, the reaction along the hydride transfer pathway is 8.9 kcal/mol. In general, the dihydrogen release pathway driven by this cyclometallated TM single-site system is less favorable than the hydride transfer pathway under acidic condition. Obviously, the hydride transfer pathway via outer-sphere mechanism is more favorable than the hydrogen release pathway for the reaction mediated by hydrated proton H_7O_3^+ .

Figure S5. The free energy profiles of hydrogen release pathway when proton source is HCOOH.

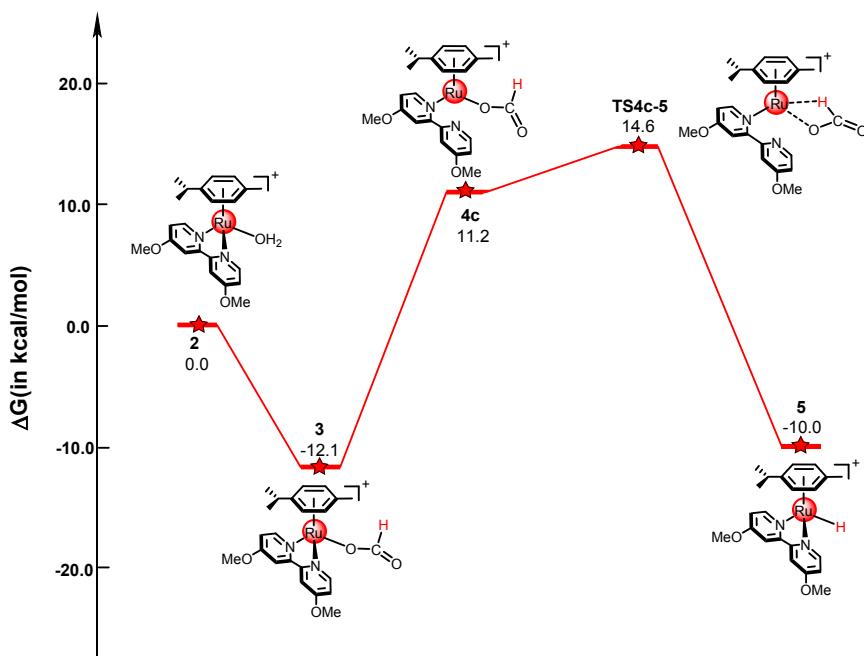

As shown in Figure S5, **TS24-25** with formic acid as proton source has an activation energy barrier of 20.3 kcal/mol, 10.9 kcal/mol higher than that of **TS14-15** with the hydrated proton $H_5O_2^+$. The calculation results suggest that the hydrogen release pathway is more favorable along $H_5O_2^+$ as proton source than formic acid as proton source.

Figure S6. The free energy profiles of TH of ketones catalyzed by cyclometallated ruthenium single-site complex when chose different basis set to describe Ru.

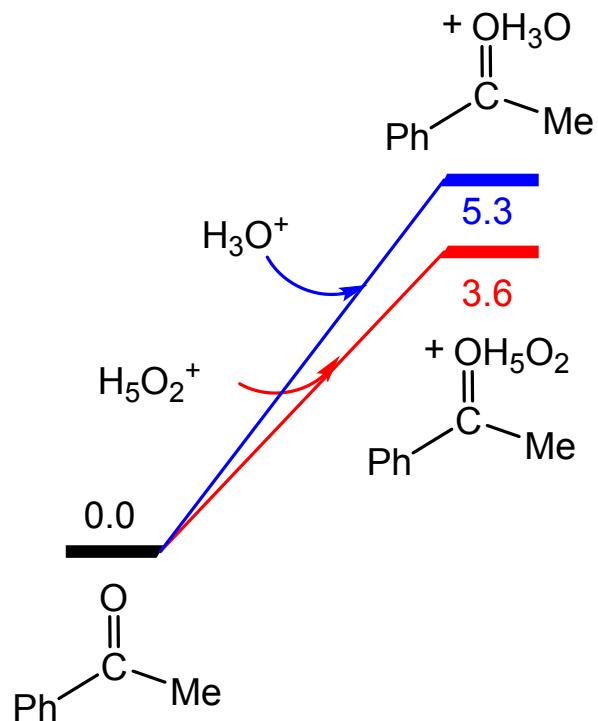

When the effective core potential (ECP) of Ru with a double- ζ valence basis set (LANL2DZ) was chosen to describe Ru, the metal hydride formation is the rate-determining step with a free energy barrier of 14.1 kcal/mol. When the sdd basis set was chosen to describe Ru, the metal hydride formation is the rate-determining step with a free energy barrier of 15.5 kcal/mol (see Figure S6). The difference of calculated results between the two basis set is little which is only 1.4 kcal/mol.

Figure S7. The free energy profiles of the formation of metal hydride 5 when the dissociation of one 4-methylpyridine.

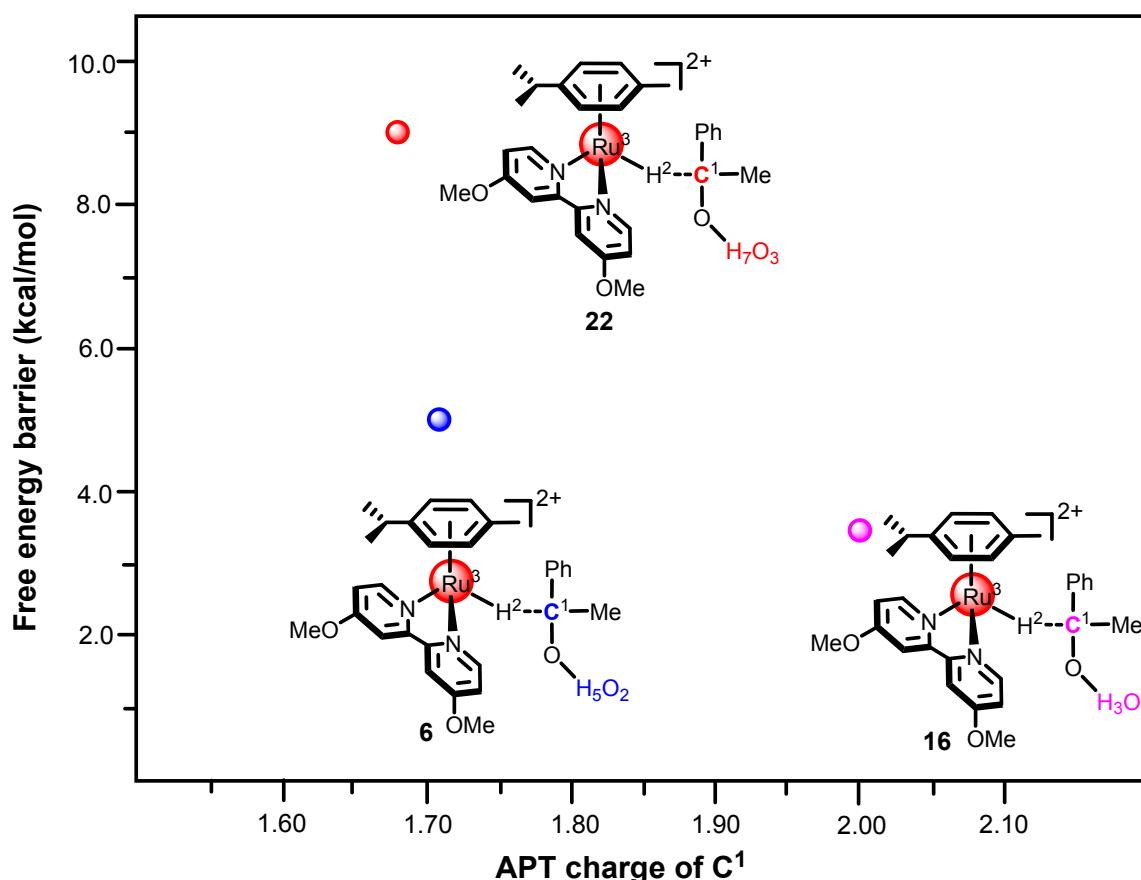

As shown in Figure S7, one 4-methylpyridine is dissociated to provide a vacant coordinate site to form complex **4c** firstly, this process is exothermic by 23.3 kcal/mol. Subsequently, the hydride transfers to Ru through **TS4c-5**, which owes an energy barrier of 26.7 kcal/mol. This high energy barrier implies that this pathway is less favorable than the ion-pair mechanism.

Figure S8. The free energy profiles of the formation of PhMeCOH₅O₂⁺ and PhMeCOH₃O⁺.

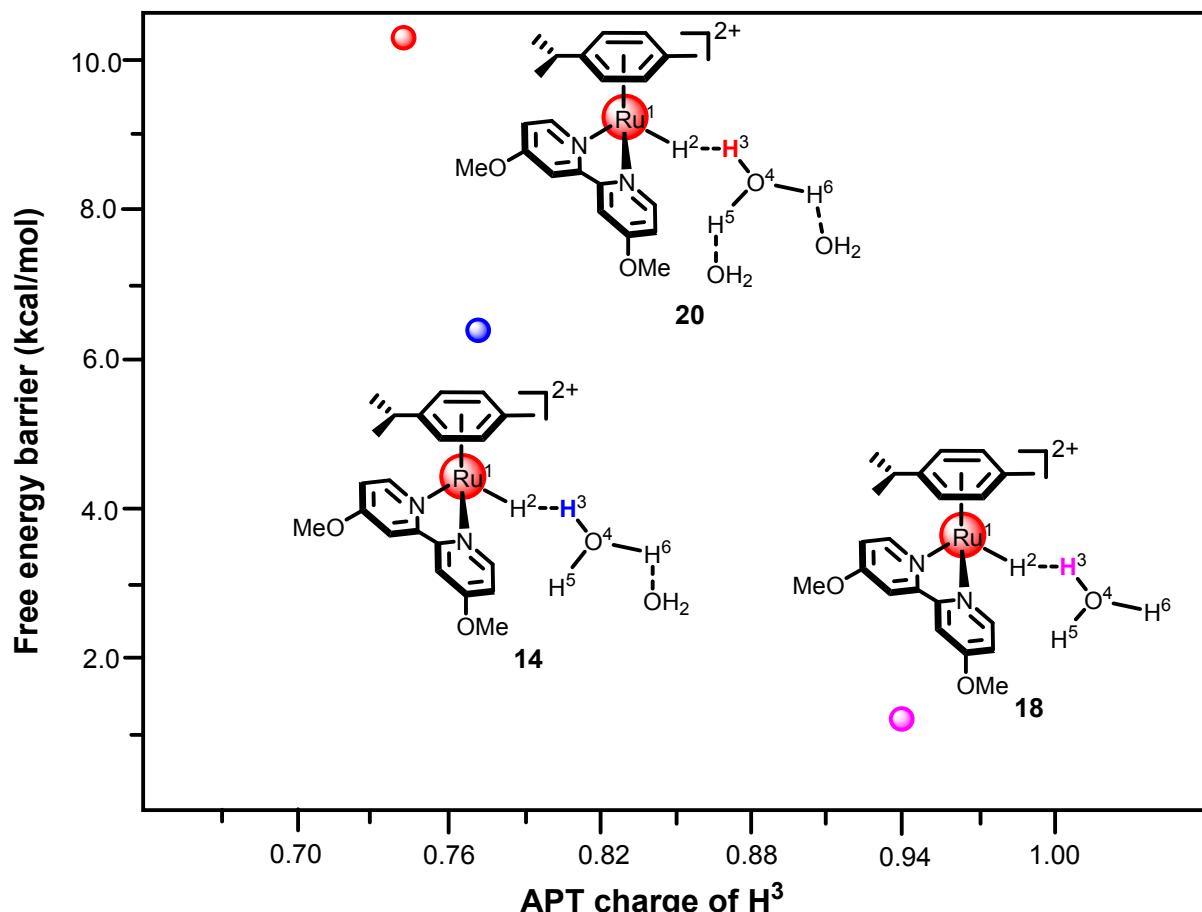

The reactions of $\text{PhMeCO} + \text{H}_5\text{O}_2^+ \rightarrow \text{PhMeCOH}_5\text{O}_2^+$ and $\text{PhMeCO} + \text{H}_3\text{O}^+ \rightarrow \text{PhMeCOH}_3\text{O}^+$ as shown in Figure S8, these processes are endergonic by 3.6 and 5.3 kcal/mol, respectively.

Figure S9. Relationship between APT charge of C¹ atom and free energy barriers of hydride transfer pathway.

As shown in Figure S9, the APT charges of C¹ in complex **22**, **6** and **16** are increasing in turn, however, the energy barriers of these pathways are decreasing in turn. It indicates that H₃O⁺ hydrated proton contributes more charges to the carbon atom of ketone. The calculated results show that the hydride transfer pathway for the reaction mediated by H₃O⁺ is more favorable than those mediated by H₅O₂⁺ or H₇O₃⁺.

Figure S10. Relationship between APT charge of H³ atom and free energy barriers of hydrogen release pathway.

As shown in Figure S10, the APT charges of H³ in complex **20**, **14** and **18** are increasing in turn, however, the energy barriers of these pathways are decreasing in turn. This means that H₃O⁺ has stronger acidity. The calculated results show that the dihydrogen release pathway for the reaction mediated by H₃O⁺ is more favorable than those mediated by H₅O₂⁺ or H₇O₃⁺.

Table S1. The APT charge of H¹ atom in hydrated protons H₃O⁺, H₅O₂⁺ and H₇O₃⁺.
