## General

All commercially available chemicals were purchased from Sigma-Aldrich and Oakwood Chemicals and used without further purification. Dry dichloromethane ( $\text{CH}_2\text{Cl}_2$ ) and tetrahydrofuran (THF) were collected from an Inert PureSolv MD5 purification system, whereas nitromethane ( $\text{MeNO}_2$ ) and acetonitrile ( $\text{MeCN}$ ) were dried with freshly activated 5 Å and 3 Å molecular sieves, respectively. Deuterated solvents ( $\text{CD}_3\text{CN}$ ,  $\text{CDCl}_3$ , and  $\text{DMSO-d}_6$ ) were purchased from Cambridge Isotope Laboratories and Sigma-Aldrich. Flash column chromatography was carried out using SiliCycle (230–400 mesh) silica gel as the stationary phase. Nuclear magnetic resonance (NMR) experiments were recorded on Bruker AVIII HD 400 MHz and Bruker Avance 400 MHz spectrometers;  $^1\text{H}$  and  $^{13}\text{C}$  NMR chemical shifts ( $\delta$ ) are given in parts per million (ppm) relative to TMS, using the residual solvent signal for calibration.  $J$  values are reported in Hz, and signal multiplicity is denoted as s (singlet), d (doublet), t (triplet), m (multiplet) and br (broad signal). UV-vis spectra were recorded on a Cary 5000 UV-vis-NIR spectrometer, employing 1 mm pathlength quartz cuvettes. High-resolution mass spectra (HRMS) were recorded on an ESI-TOF Waters Micromass LCT spectrometer. Cyclic voltammograms were acquired using an AFCBP1 potentiostat from Pine Instrument company. Macrocycle **DN32C8**,<sup>1</sup> and precursors **C-21**<sup>2</sup> and **C-22**,<sup>3</sup> were synthesized following reported methodologies and all spectroscopic characterization matched with the published data.

## Ring-size comparison

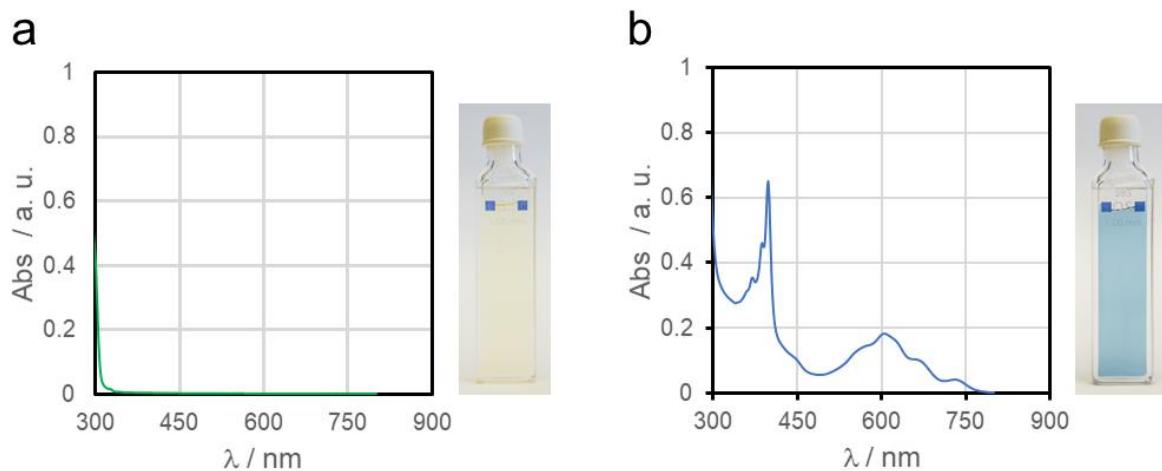

Figure S1 shows the macrocycles ***trans*-21C6**, ***trans*-22C6** and **DN32C8** as found in reported [2]rotaxane structures.<sup>1,2</sup>

**Figure S1.** Solid-state structures of the chosen macrocyclic scaffolds. The thread species hosted in their cavities have been omitted for clarity.

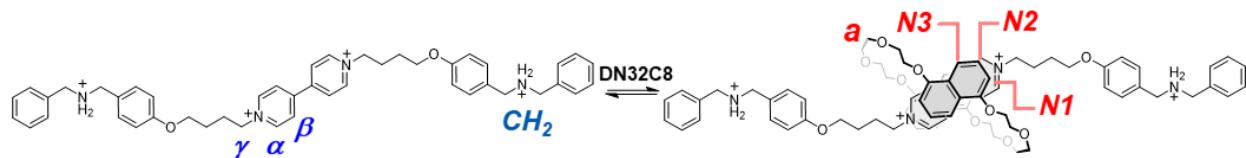

## Viologen reduction

A deaerated solution of viologen  $[1\cdot H_2][PF_6]_4$  in MeCN ( $2 \times 10^{-3}$  M, 400  $\mu$ L) was loaded with zinc dust (10 mg) and stirred for 10 min under a N<sub>2</sub> atmosphere, causing the solution to change color from yellow to blue. Figure S2 shows the UV-vis spectra of the viologen before and after its reduction. Radical cation was identified by two structured bands at  $\lambda_{max}$  ( $\epsilon$ ) of 400 (2560) and 610 nm ( $720 \text{ mol}^{-1} \text{ dm}^3 \text{ cm}^{-1}$ ).

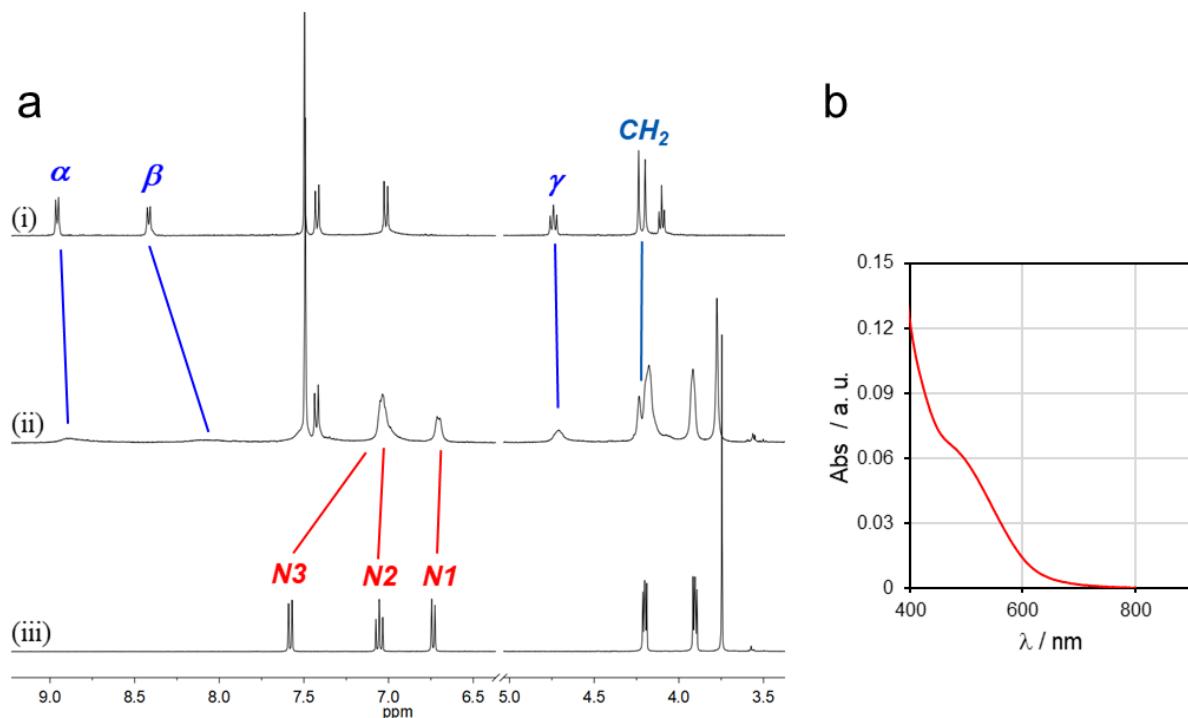

**Figure S2.** UV-vis spectra (MeCN, 25 °C) of  $[1\cdot H_2][PF_6]_4$  a) before and b) after chemical reduction with Zn<sup>0</sup>. The photographs show the analyzed samples.

## Self-assembly of pseudorotaxane $[1 \cdot H_2 \subset (21C6)_2]^{4+}$

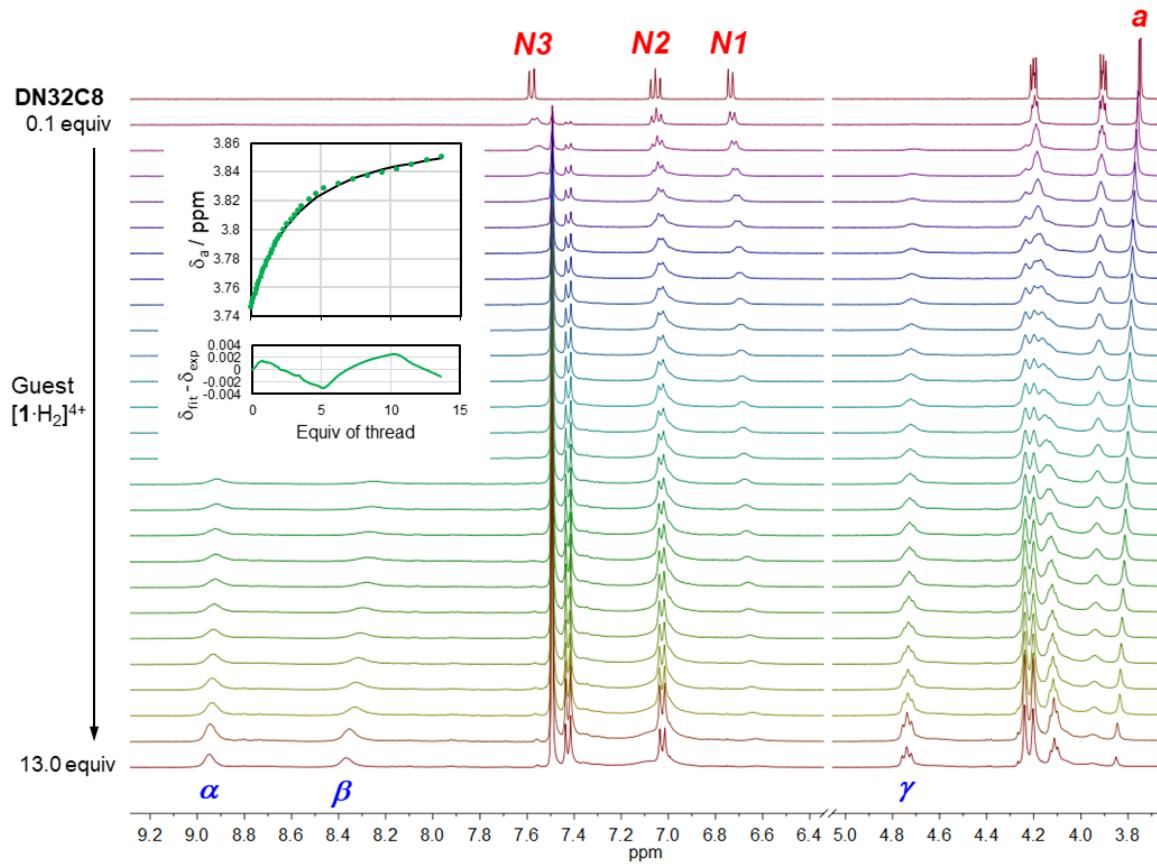

**Scheme S1.** [2]pseudorotaxane formation and proton assignment.

The thread molecule  $[1 \cdot H_2][PF_6]_4$  and macrocycle **DN32C8** were mixed in a 1:1 ratio in  $CD_3CN$  (or MeCN) and analyzed by  $^1H$  NMR, UV-vis spectroscopy, and high-resolution mass spectrometry. Changes in the NMR data (Figure S3a), for both the host and guest resonances, suggest the formation of the [2]pseudorotaxane  $[1 \cdot H_2 \subset (21C6)_2]^{4+}$ , which is stabilized by  $\pi\text{-}\pi$  stacking interactions. UV-vis spectroscopy reveals an absorption band centered at 475 nm (Figure S3b), which is ascribed to the formation of a charge transfer complex within the pseudorotaxane. Additionally, the parent ion  $[1 + DN32C8 + 2H + 2PF_6]^{2+}$  was detected by HRMS at  $m/z = 766.2969$  (calc. 766.2971, error = -0.2 ppm).

**Figure S3.** a) Partial  $^1H$  NMR spectra (400 MHz,  $CD_3CN$ ) of (i) guest  $[1 \cdot H_2][PF_6]_4$ , (ii) an equimolar mixture of **DN32C8** and  $[1 \cdot H_2][PF_6]_4$  ( $2 \times 10^{-3}$  M), and (iii) macrocycle **DN32C8**. b) UV-visible spectrum (MeCN, 25 °C) of a 1:1 mixture of guest and host ( $5 \times 10^{-3}$  M).

On the other hand,  $K_{\text{asso}}$  for pseudorotaxane  $[1 \cdot H_2 \subset \mathbf{DN32C8}] [PF_6]_4$  was determined by titration of macrocycle **DN32C8** with thread  $[1 \cdot H_2] [PF_6]_4$  in  $CD_3CN$  at 298 K, and probed by  $^1H$  NMR spectroscopy (Figure S4).

**Figure S4.**  $\mathbf{DN32C8}$  ( $2 \times 10^{-3}$  M) titration with thread  $[1 \cdot H_2] [PF_6]_4$  in  $CD_3CN$  ( $4 \times 10^{-2}$  M); experiment monitored by  $^1H$  NMR spectroscopy (400 MHz,  $CD_3CN$ ) at 298 K. The insert contains a selected titration isotherm plotted for proton  $a$  from  $\mathbf{DN32C8}$ ; experimental data (green dots), fitted data (black line). The residual plot is also included.

The resulting isotherms were fit by a nonlinear least-squares method using the BindFit platform (supramolecular.org), and using a 1:1 global fitting model (Nelder-Mead method).  $\Delta G_{\text{asso}}$  was determined by applying Eq. 1. Table S1 contains the obtained thermodynamic data.

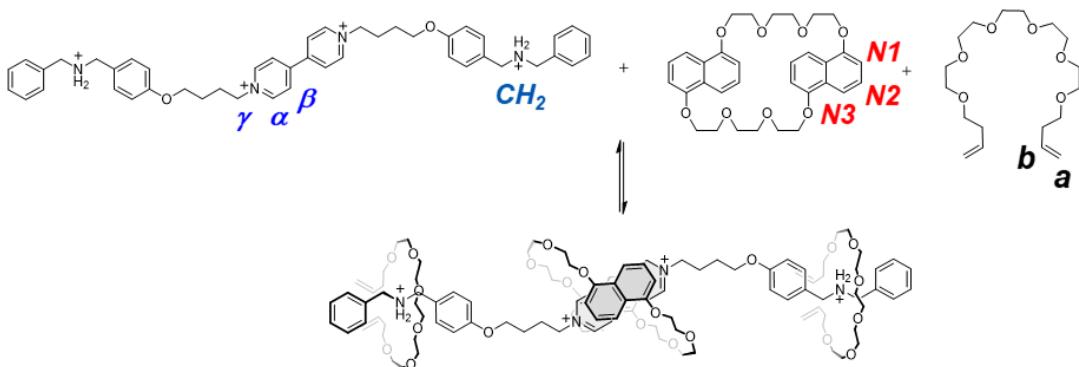

$$\text{Eq. 1} \quad \Delta G_{\text{asso}} = -RT \ln K_{\text{asso}}$$

**Table S1.** Thermodynamic parameters corresponding to the [2]pseudorotaxane complex in  $CD_3CN$  at 298 K.

Complex	$K_{\text{asso}} / M^{-1}$	$\Delta G_{\text{asso}} / kJ \text{ mol}^{-1}$
$[1 \cdot H_2 \subset \mathbf{DN32C8}]^{4+}$	$(1.72 \pm 0.03) \times 10^2$	$-12.8 \pm 0.2$

\*Standard deviations were calculated from three independent experiments

## Self-sorting process

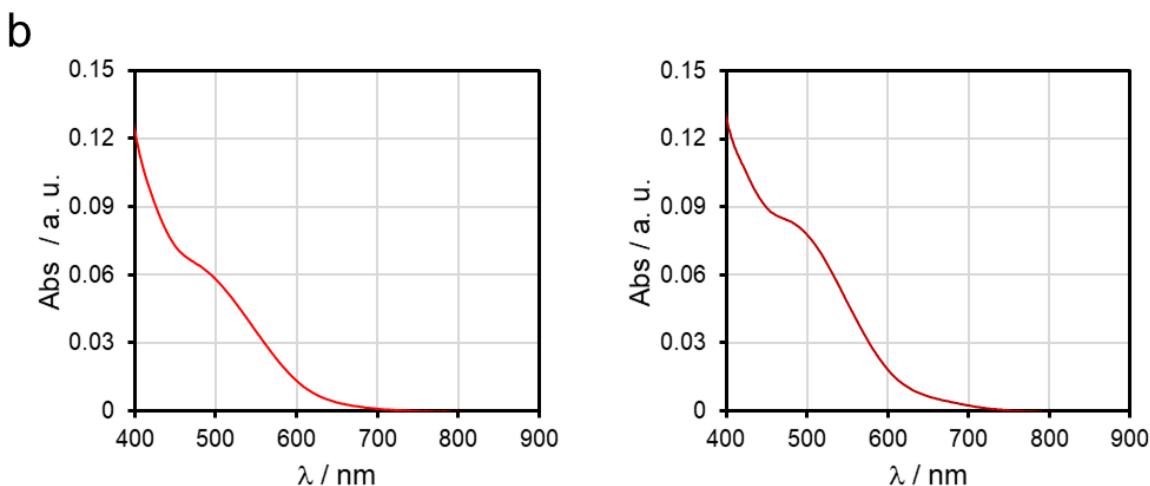

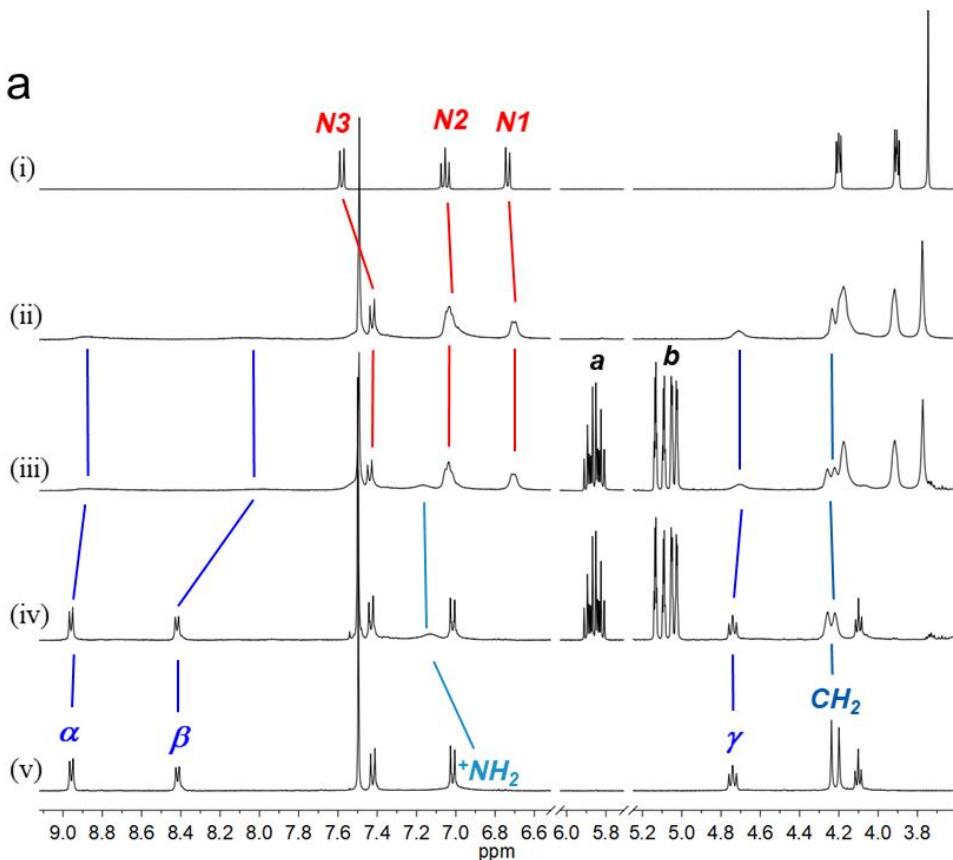

**Scheme S2.** Self-sorting process of thread, macrocycle and tether **C-22**. Proton assignment is included.

The self-sorting process of the thread molecule  $[1 \cdot H_2][PF_6]_4$ , macrocycle **DN32C8**, and the glycol precursors **C-21** and **C-22** was analysed by UV-vis and  $^1H$  NMR spectroscopy in acetonitrile solutions. Figure S5 shows a representative example for the system assembled with **C-22**.

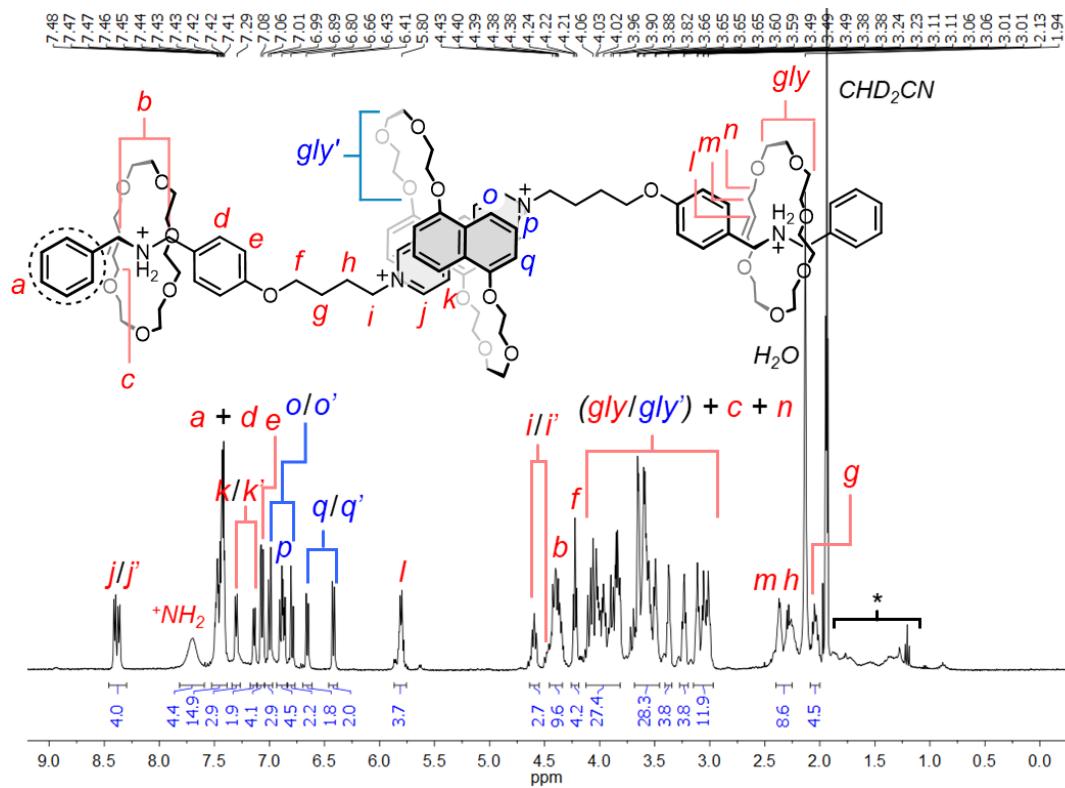

Mixing  $[1 \cdot H_2][PF_6]_4$  with **DN32C8**, in a 1:1 ratio ( $5 \times 10^{-3}$  M), resulted in a red solution, a color change ascribed to the formation of a charge-transfer complex with an absorbance band at 475 nm in the UV-vis spectrum (Figure S5c). In the  $^1H$  NMR spectrum, only the bipyridinium resonances ( $\alpha$  and  $\beta$ ) showed significant changes (Figure S5a, ii), e.g.  $\alpha$  moves to lower frequency and gets broader, indicating that the ring encircles only the central portion of  $[1 \cdot H_2]^{4+}$ . In a separate experiment,  $[1 \cdot H_2][PF_6]_4$  ( $5 \times 10^{-3}$  M) was mixed with two equiv of **C-22** and no color change was registered. In the corresponding NMR spectrum (Figure S5a, iv), only the  $^+NH_2$  resonance registered a change while the pyridinium proton signals remained unaltered; this suggests that **C-22** wraps exclusively around the ammonium stations.

Mixing  $[1 \cdot H_2][PF_6]_4$ , **DN32C8**, and **C-22** in a 1:1:2 ratio resulted in a self-sorting process, i.e. **DN32C8** sits on the central recognition site of  $[1 \cdot H_2]^{4+}$  while **C-22** interacts with the ammonium end-groups, this was confirmed by the observed matching of all chemical shifts in the  $^1H$  NMR (Figure S5a, iii) with respect to the two previously analyzed systems (*vide supra*). Moreover, the UV-vis band at 475 nm was detected with no detriment (Figure S5b).

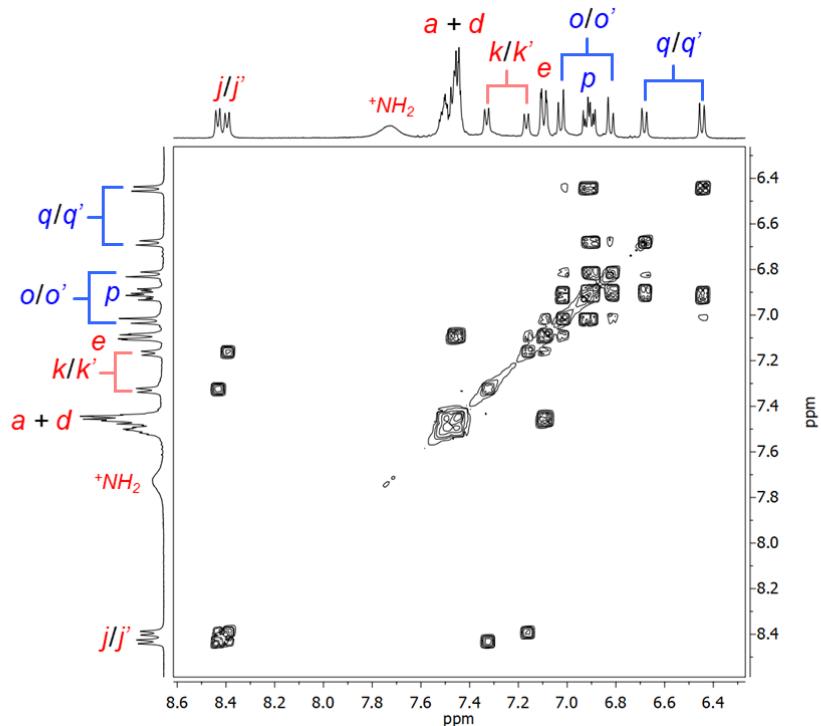

**Figure S5.** a) Partial <sup>1</sup>H NMR spectra (400 MHz, CD<sub>3</sub>CN) of (i) macrocycle **DN32C8**, (ii) an equimolar mixture of thread and macrocycle **DN32C8** ( $5 \times 10^{-3}$  M), (iii) a solution of **DN32C8**, [1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>, and **C-22** in a 1:1:2 ratio; **[DN32C8]** =  $5 \times 10^{-3}$  M, (iv) a 2:1 mixture of **C-22** and [1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>; **[C-22]** =  $1 \times 10^{-2}$  M, and (v) thread [1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>. b) UV-vis spectrum of a solution (MeCN) containing pseudorotaxane  $[1\text{-H}_2\subset\text{DN32C8}]^{4+}$  ( $5 \times 10^{-3}$  M) before (left) and after the addition of two equivalents of **C-22** (right).

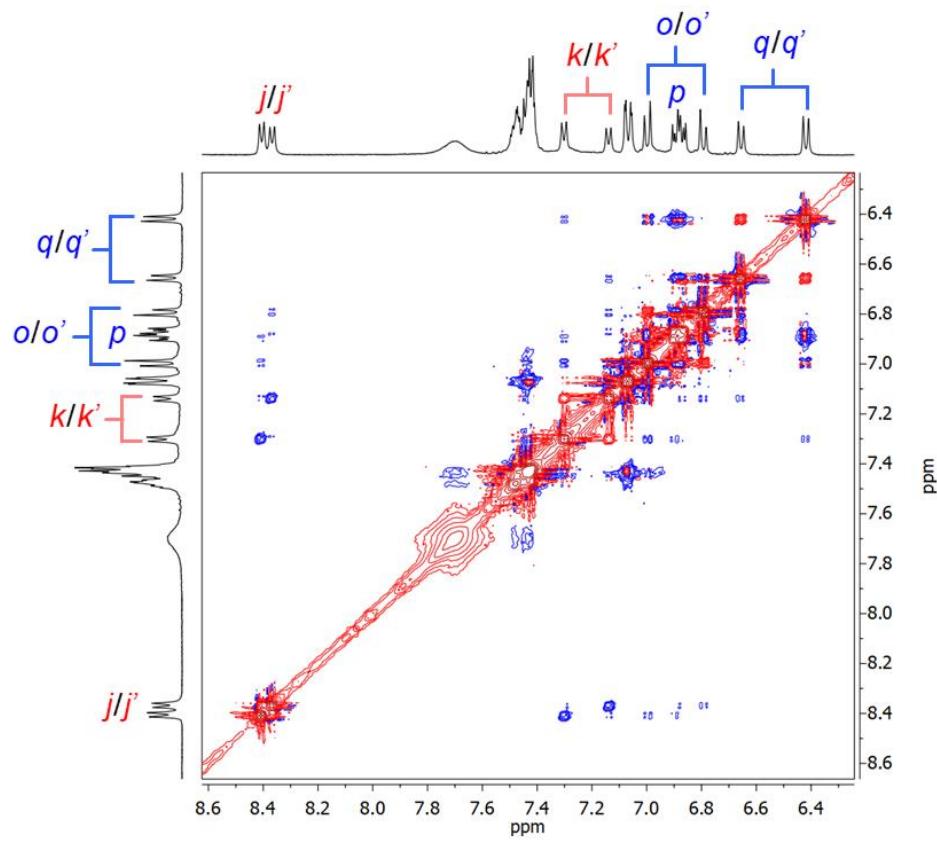

## Selected NMR characterization of *p*-H[4]R

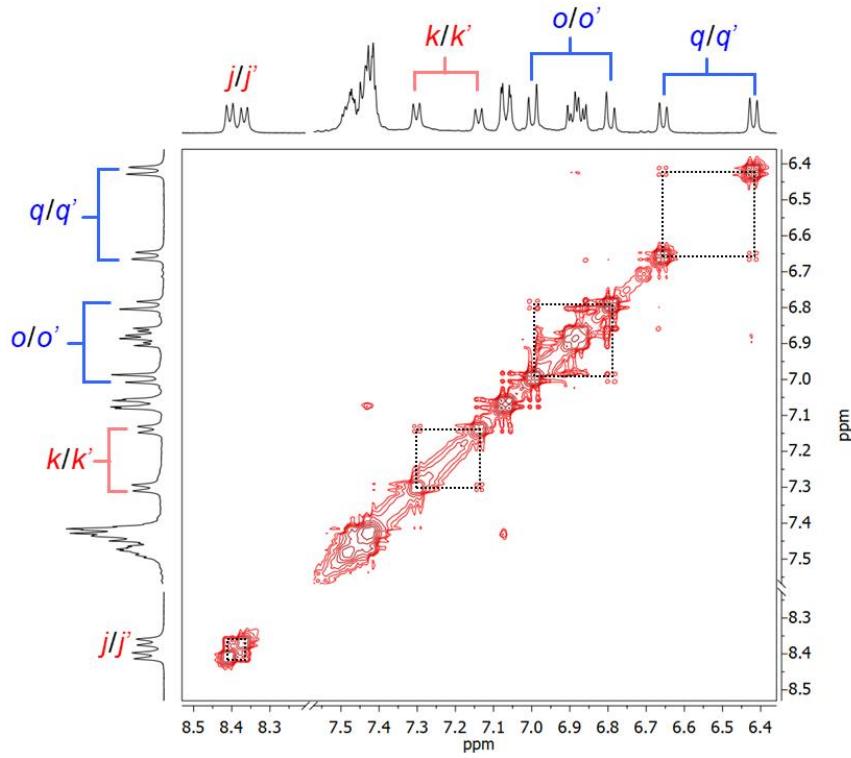

**Figure S6.**  $^1\text{H}$  NMR spectrum (400 MHz,  $\text{CD}_3\text{CN}$ ) of hetero[4]rotaxane *p*-H[4]R. \* Denotes hexanes and AcOEt.

**Figure S7.** Partial (aromatic region)  $^1\text{H}$ - $^1\text{H}$  COSY NMR spectrum (400 MHz,  $\text{CD}_3\text{CN}$ ) of *p*-H[4]R.

**Figure S9.** Partial  $^1\text{H}$ - $^1\text{H}$  EXSY NMR spectrum (400 MHz,  $\text{CD}_3\text{CN}$ ) of  $p\text{-H[4]R}$ .

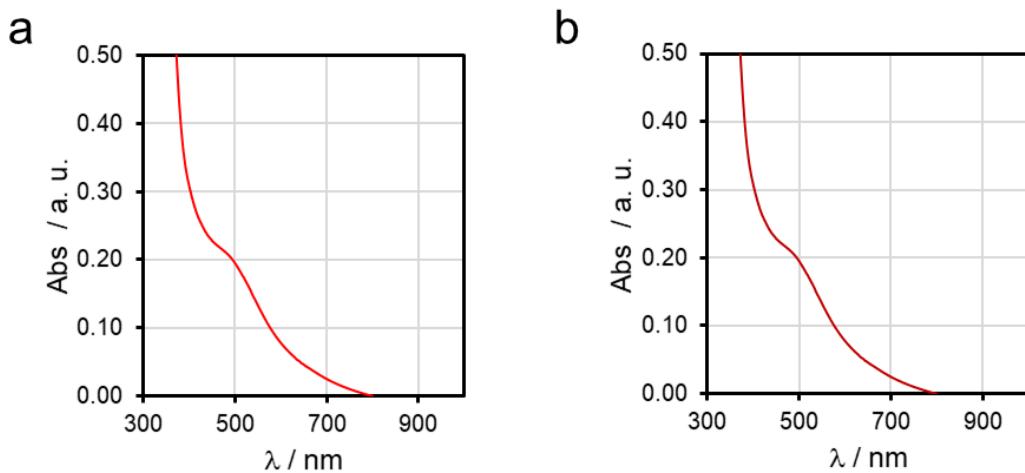

**$^1\text{H}$  NMR spectrum of a model [3]rotaxane**

**Figure S10.**  $^1\text{H}$  NMR spectrum (400 MHz,  $\text{CD}_3\text{CN}$ ) of [3]rotaxane [ $1\cdot\text{H}_2\subset(21\text{C}6)_2\right]\text{[PF}_6\text{]}_4$ . \* Denotes grease.

## Reduction attempts on the hetero[4]rotaxane structures

Acetonitrile solutions (300  $\mu\text{L}$ ,  $1 \times 10^{-3}$  M) of **p-H[4]R** and **t-H[4]R** were sparged with  $\text{N}_2$ , and loaded with zinc dust (10 mg). The samples were analyzed by UV-vis spectroscopy just after adding the reducing agent and one hour later. See a representative result for **t-H[4]R** in Figure S11.

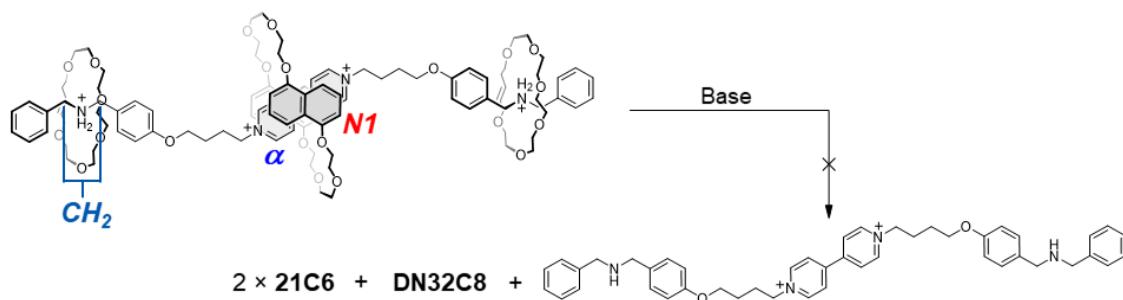

**Figure S11.** UV-vis spectra ( $\text{CH}_3\text{CN}$ , 25 °C) for the attempted reduction of **t-H[4]R** using  $\text{Zn}^0$ . (a) Just after adding zinc dust and (b) one hour later.

## Unstopping attempts on *p*-H[4]R

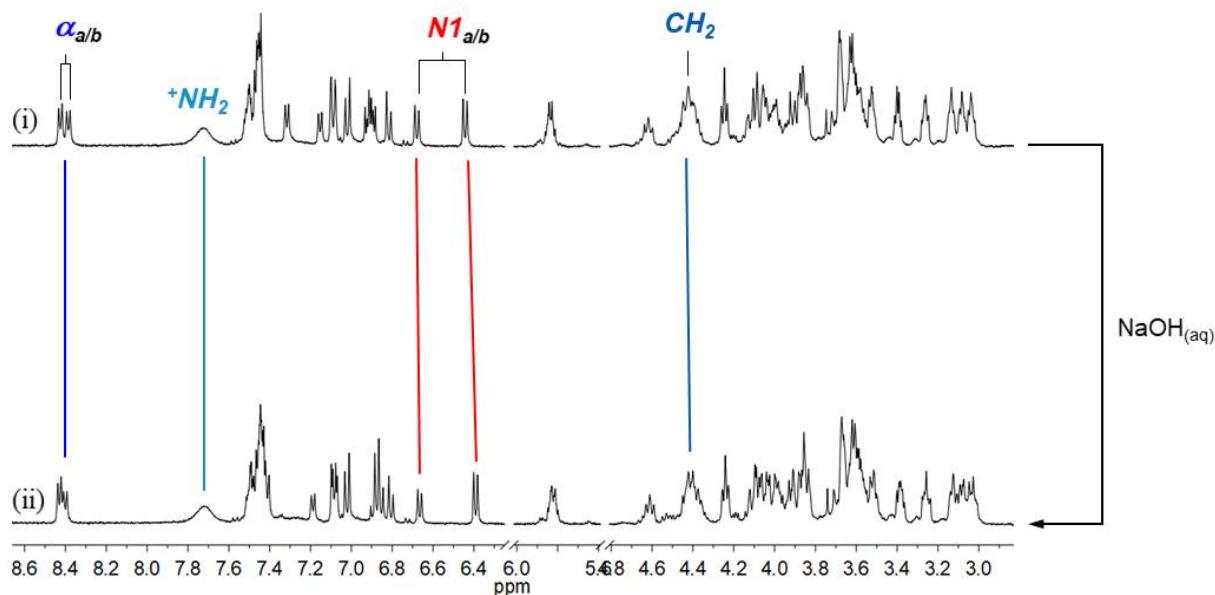

Solutions of rotaxane *p*-H[4]R at  $1 \times 10^{-3}$  M concentration were analyzed towards three different stimuli: base, polarity, and heat.

### Base trigger

**Scheme S3.** Attempted unstopping of *p*-H[4]R using base as a trigger.

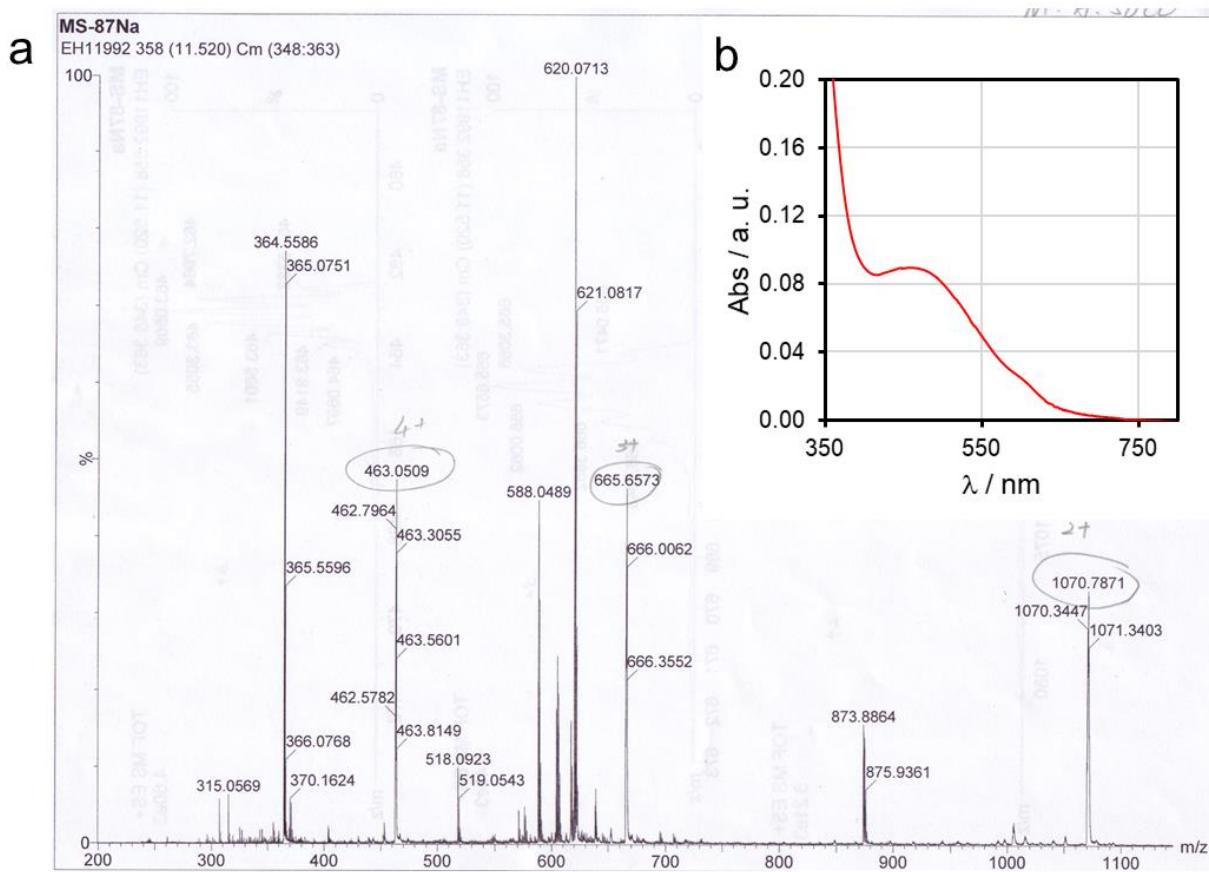

An alkaline solution (1 M, 1 equiv,  $\text{NaOH}_{(\text{aq})}$ ) was added to a  $\text{CD}_3\text{CN}$  solution of *p*-H[4]R and stirred for 10 min at room temperature. The  $^1\text{H}$  NMR data collected at this point is shown in Figure S12.

**Figure S12.** Partial  $^1\text{H}$  NMR spectra (400 MHz,  $\text{CD}_3\text{CN}$ ) of *p*-H[4]R (i) before and (ii) after the addition of one equivalent of base (1 M  $\text{NaOH}_{(\text{aq})}$ ). Selected resonances have been labeled.

From the experiment, it is evident that the  $^+NH_2$  resonance is present after the addition of base. The chemical shifts of the remaining signals suggest that the hetero[4]rotaxane stays (in both isomeric forms) unaltered in solution. Only slight changes were noticed that might be attributed to the presence of water and  $Na^+$  ions coming from the added alkaline solution.

UV-vis spectroscopy (see band at 490 nm) and HRMS ( $m/z = 463.0509$ ,  $665.6573$ , and  $1070.7871$ ) further confirmed that **p-H[4]R** remains in solution, see Figure S13.

**Figure S13.** a) HRMS for a sample of **p-H[4]R** treated with one equiv of  $NaOH_{(aq)}$ . Ions  $[1 + DN32C8 + (2 \times 21C6) + 2H]^4+$ ,  $[1 + DN32C8 + (2 \times 21C6) + 2H + PF_6]^{3+}$ , and  $[1 + DN32C8 + (2 \times 21C6) + 2H + 2PF_6]^{2+}$  are detected at  $m/z$   $463.0509$ ,  $665.6573$ , and  $1070.7871$ , respectively. The free components as  $[DN32C8 + Na]^+$  (calc.  $m/z = 571.2302$ ),  $[1]^2+$  (calc.  $m/z = 346.2040$ ), and  $[21C6 + Na]^+$  (calc.  $m/z = 327.1778$ ) were not observed. Peak at  $m/z = 364.5586$  might correspond to a fragmented portion of **p-H[4]R**, i.e. a viologen containing the oxybutylene chain and the mechanical stopper only on one  $N$ -position (calc.  $m/z = 364.7171$ ). Peaks at  $m/z = 588.0489$ ,  $m/z = 620.0713$ , and  $m/z = 873.8864$  do not correspond to any envisioned fragmentation product. b) UV-vis spectrum (MeCN) of **p-H[4]R** treated with one equiv of base.

## Polarity and temperature effect

When a solution of rotaxane **p-H[4]R** was prepared in DMSO-*d*<sub>6</sub> and analyzed at room temperature over a period of one month, no changes were observed. A representative <sup>1</sup>H spectrum is shown in Figure S14. As observed in CD<sub>3</sub>CN, two isomers are distinguished in DMSO-*d*<sub>6</sub>; however, their relative concentrations correspond to 2:1 according to the <sup>1</sup>H NMR integrals.

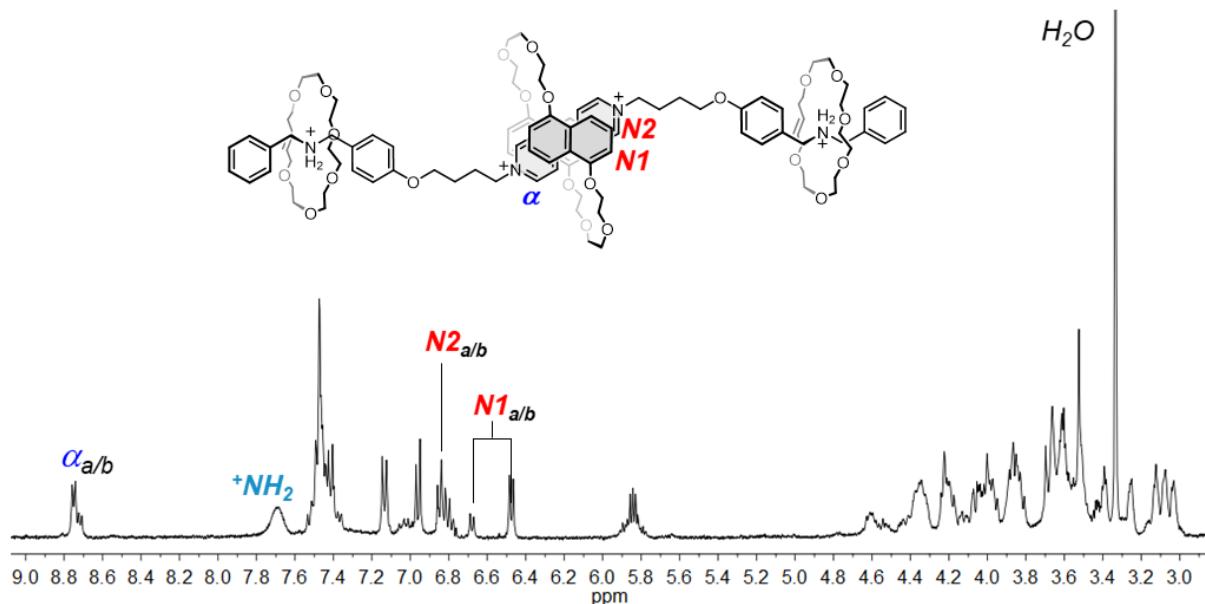

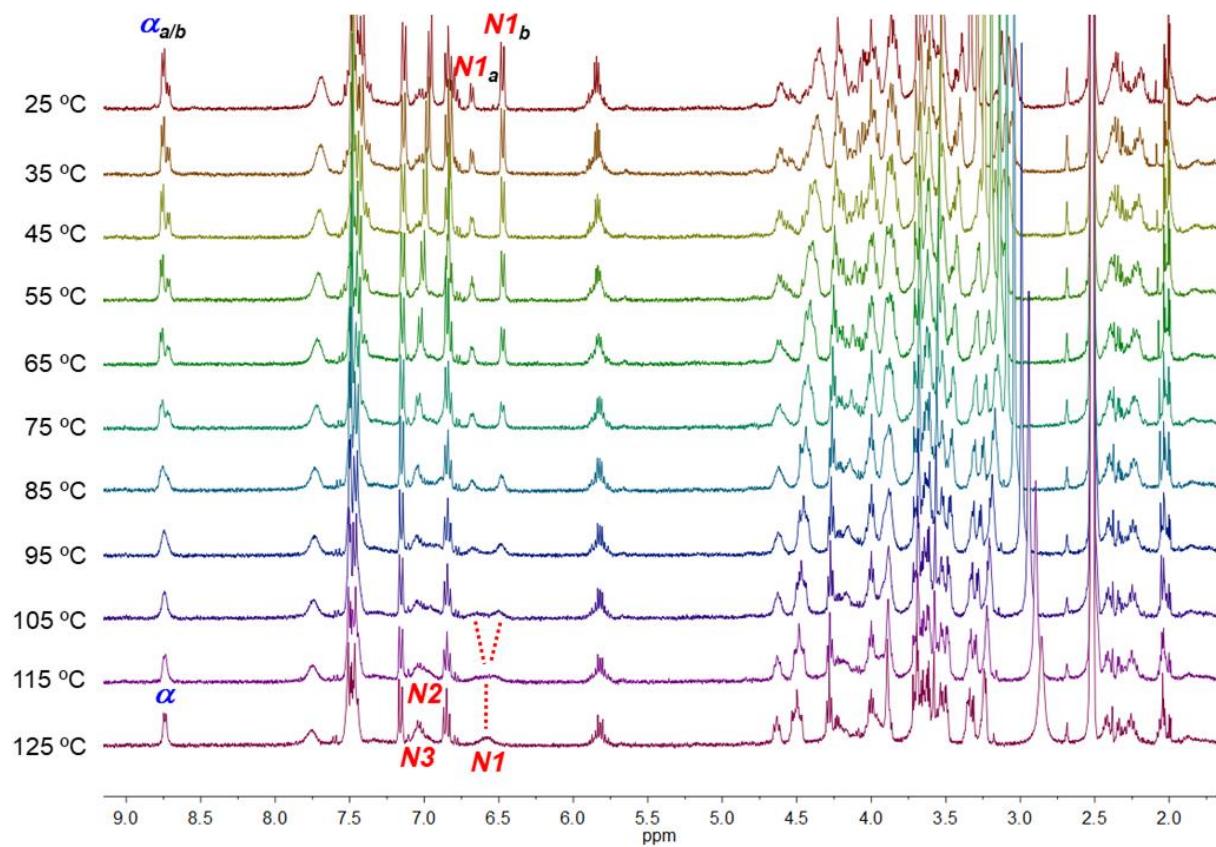

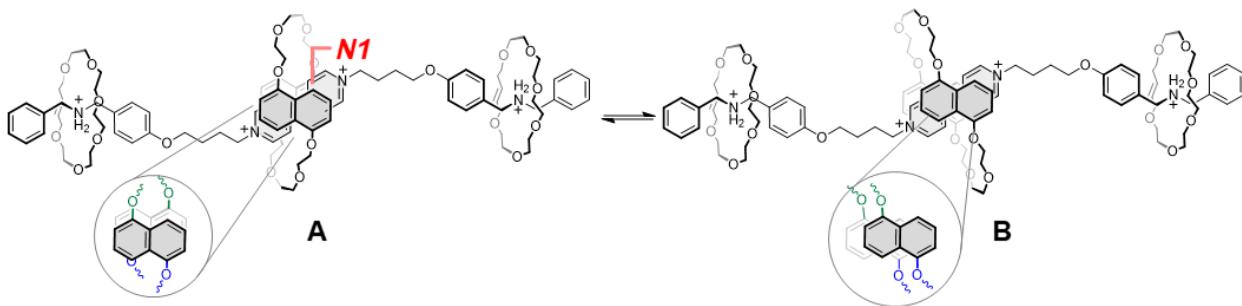

Figure S14. <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) of rotaxane **p-H[4]R** after 1 month of storage.

Heating the DMSO-*d*<sub>6</sub> sample did not produce significant effects. Elevated temperatures only caused faster isomer interconversion as suggested by the <sup>1</sup>H NMR spectra collected from 25 °C to 125 °C (Figure S15).

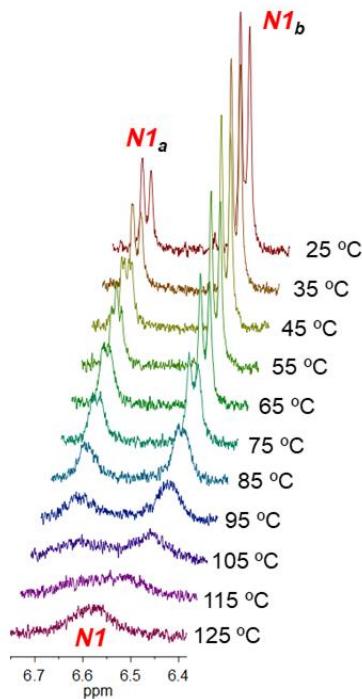

**Figure S15.** VT-NMR spectra (400 MHz, DMSO-*d*<sub>6</sub>) for compound **p-H[4]R**. Selected resonances are labeled.

## Isomer interconversion process

**Scheme S4.** Isomer interconversion.

To estimate the energy barriers between isomers **A** and **B** (interconverted by the rotation of one naphthalene motif (Np) along the RO–Np–OR axis), we employed the coalescence temperature method.<sup>4</sup> Resonances  $N1_a$  and  $N1_b$  were monitored by  $^1\text{H}$  NMR in  $\text{DMSO}-d_6$  from 25 to 125 °C (Figure S16).

**Figure S16.** Partial VT-NMR spectra (400 MHz,  $\text{DMSO}-d_6$ ) of compound **p-H[4]R**.

At the coalescence temperature (115 °C) the exchange rate of the isomers is given by

$$k = \frac{\pi(\Delta\nu)}{\sqrt{2}}$$

where  $k$  is the exchange rate constant and  $\Delta\nu$  is the limiting chemical shift between the exchanging resonances. For our system a  $k$  of  $110\text{ s}^{-1}$  was found. The values of the free activation energies for each isomer were obtained using Eyring's equation:

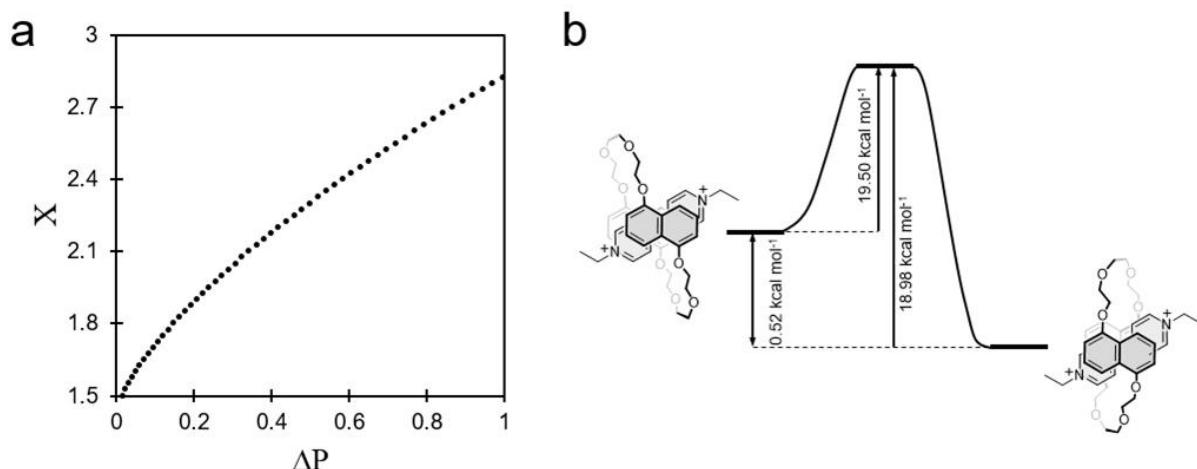

$$\Delta G_{\mathbf{A}}^{\neq} = RT_c \ln \left[ \frac{k_B}{\pi h} \left( \frac{T_c}{\delta\nu} \right) \left( \frac{X}{1-\Delta P} \right) \right]$$

$$\Delta G_{\mathbf{B}}^{\neq} = RT_c \ln \left[ \frac{k_B}{\pi h} \left( \frac{T_c}{\delta\nu} \right) \left( \frac{X}{1+\Delta P} \right) \right]$$

where  $T_c$  is the coalesce temperature (388 K),  $R$  is the gas constant ( $1.986 \times 10^{-3}\text{ kcal mol}^{-1}$ ),  $h$  is Planck's constant ( $1.584 \times 10^{-37}\text{ kcal s}$ ),  $k_B$  is the Boltzmann's constant ( $3.299 \times 10^{-27}\text{ kcal K}^{-1}$ ),  $\delta\nu$  is the limiting chemical shift for the isomer signals at slow exchange (80 Hz at 298 K), and  $\Delta P$  is the mole fraction difference between isomers **A** ( $\chi_A = 0.66$ ) and **B** ( $\chi_B = 0.33$ );  $\Delta P = 0.33$ . Parameter X was obtained via iteration of

$$\Delta P = \left( \frac{X^2 - 2}{3} \right)^{3/2} \times \frac{1}{X}$$

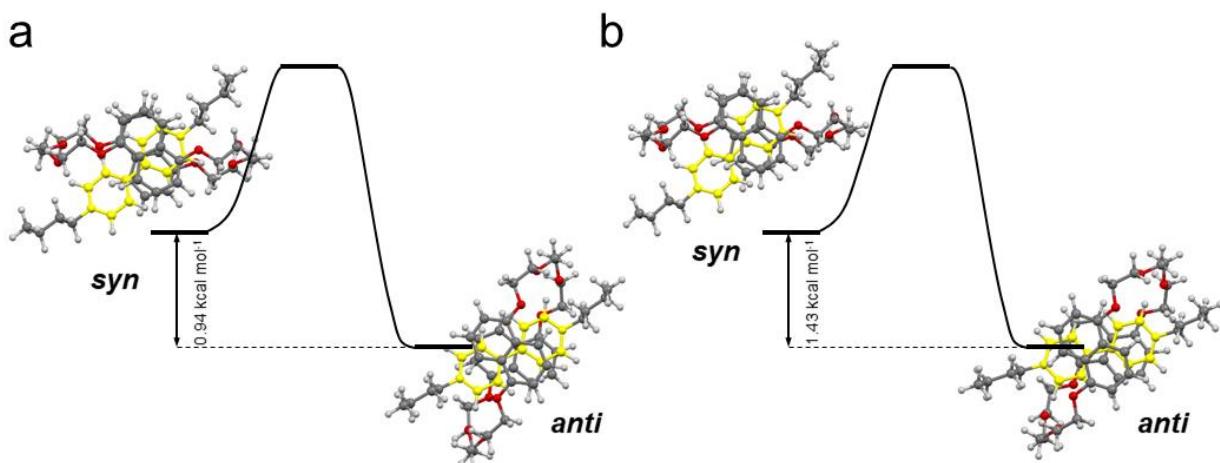

(see Figure S17a for reference),  $X = 2.09$  at  $\Delta P = 0.33$ . The interconversion found barrier energies correspond to  $19.5\text{ kcal mol}^{-1}$  and  $19.0\text{ kcal mol}^{-1}$ , which implies a free energy difference ( $\Delta G$ ) of  $0.5\text{ kcal mol}^{-1}$  (Figure S17b).

**Figure S17.** (a) Plot showing the iteration of parameter X. (b) Isomer representation and their relative energies.

Although other dynamic processes occurring within the hetero[4]rotaxanes cannot be excluded (such as short-rage shuttling and pirouetting), we rationalize that the *anti/syn* isomerization would be the only solvent-dependent process yielding different ratios of **A** and **B** in CD<sub>3</sub>CN (1:1) and DMSO-d<sub>6</sub> (2:1).

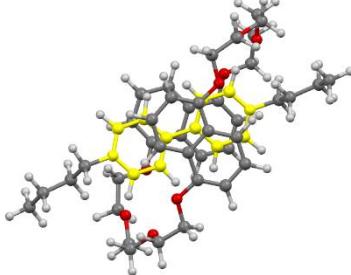

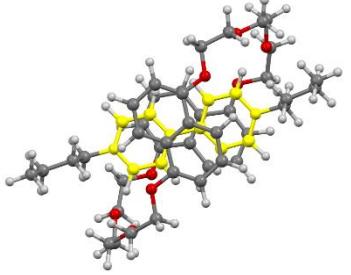

Further computations demonstrated that the *anti*-**DN32C8** ring renders a more stable interlocked species when compared to the corresponding *syn* isomer. The computed energy difference for both isomers, using a **DN32C8/n**-butyl viologen system as a model, corresponds to 0.94 kcal mol<sup>-1</sup>, in close agreement with the experimental observations in DMSO. Computed data in MeCN, as explicit solvent, produced similar results (1.43 kcal mol<sup>-1</sup>), see Figure S18.

**Figure S18.** Computed syn/anti isomers and their relative energies in (a) DMSO and (b) MeCN. The viologen motif, as part of an *n*-butyl viologen, is represented in yellow.

These results were obtained with the Gaussian suite of program G016.revB01.<sup>5</sup> Geometries have been computed with the range separated dispersion corrected (wB97xD)<sup>6</sup> xc functional. Basis set for all atoms was 6-31g(d).<sup>7</sup> All structures were checked for being minima by computing the Hessian matrix at the same level of theory. All integrals were computed using the “Ultrafine” integration grid. Calculations were performed in solvent (MeCN and DMSO) using the SCRF (Self Consistent Reaction Field) approach for continuum solvent model simulation included in the Gaussian suite of programs (see data in Table S2–Table S4).<sup>8</sup> Reported SCXRD geometries<sup>1,9</sup> were used as input guesses for the optimization, increasing all the bond distances involving hydrogen atoms to 1.07 Å and adding the *n*-butyl side chains to the N and N' positions of the viologen moiety.

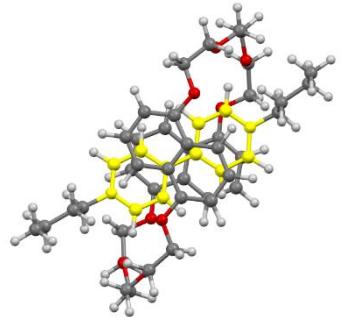

**Table S2.** Cartesian coordinates of the *anti*-DN32C8/n-butyl viologen complex in its two most stable conformations (MeCN).

## Deprotection attempt on *p*-H[4]R

**Scheme S5.** Deprotection attempted on rotaxane *p*-H[4]R via polarity effect.

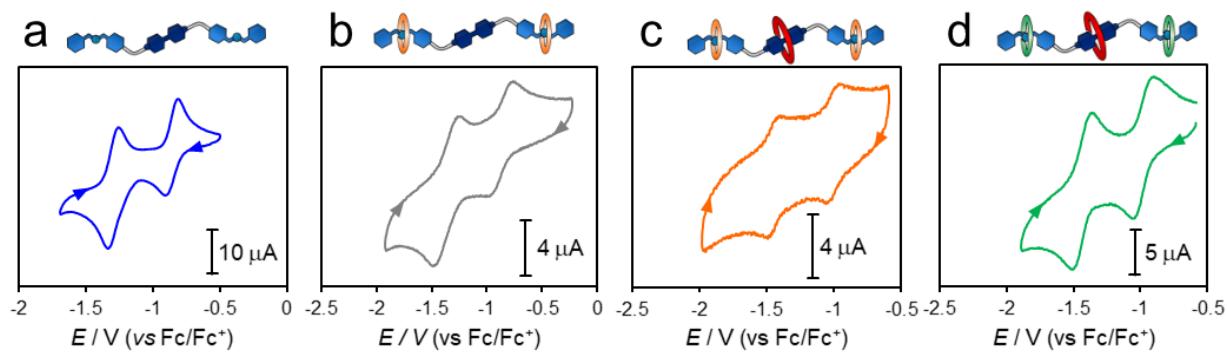

A sample of *p*-H[4]R in DMSO (1 mL,  $2 \times 10^{-3}$  M) was loaded with zinc dust (50 mg) and stored over 6 months at room temperature in a N<sub>2</sub> glove box. Figure S19 shows the UV-vis spectra for the initial and final stages, where no significant differences are observed. This confirms that the hetero[4]rotaxane remains assembled, with the substrate permanently protected.

**Figure S19.** UV-vis spectra of *p*-H[4]R in DMSO, a) before mixing with Zn<sup>0</sup>, and b) after storing for 6 months in the presence of Zn<sup>0</sup> under a N<sub>2</sub> atmosphere. The photographs show the collected samples.

## Cyclic voltammetry analyses

Voltammograms of  $[1\cdot H_2][PF_6]_4$ ,  $[1\cdot H_2\subset(21C6)_2][PF_6]_4$ , **p-H[4]R**, and **t-H[4]R** were recorded in MeCN, employing  $n$ -Bu<sub>4</sub>NPF<sub>6</sub> as the electrolyte (100 mM) at 25 °C, and at a sweep rate of 100 mV/s. The working electrode was a glassy carbon disc (~0.5 mm in diameter), the counter electrode consisted of a platinum mesh, and the pseudo-reference electrode was a silver wire. The ferrocene (Fc) / ferrocenium (Fc<sup>+</sup>) redox couple was used to reference all measurements.

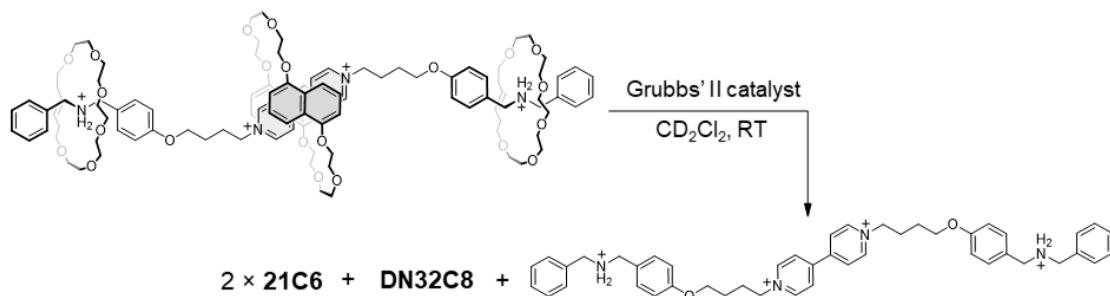

**Figure S20.** Cyclic voltammograms of the unprotected species a)  $[1\cdot H_2]^{4+}$  (1.0 mM) and b)  $[1\cdot H_2\subset(21C6)_2]^{4+}$  (1.0 mM), and the protected systems c) **p-H[4]R** (0.1 mM) and d) **t-H[4]R** (1.0 mM). Arrows indicate the sweep direction.

As shown in Figure S20, all cyclic voltammograms showed a reversible two-electron process for the reduction of the viologen substrate. As expected, the half-wave potentials ( $E^1_{1/2}$  and  $E^2_{1/2}$ , summarized in Table S5) of the unprotected species, thread  $[1\cdot H_2]^{4+}$  and [3]rotaxane  $[1\cdot H_2\subset(21C6)_2]^{4+}$ , are equivalent; *i.e.*  $E^1_{1/2}$  is -0.86 V in both cases (as for the formation of the corresponding radical trications). In contrast, the presence of the protecting unit (**DN32C8**) in **p-H[4]R** and **t-H[4]R** produces a cathodic shift of ~140 mV for the same redox pair. This can be ascribed to the stabilization effect of **DN32C8** to the viologen as result of a charge transfer process within the rotaxane structures, *i.e.* from the electron-rich ring to the electron-poor substrate. This stabilization effect was calculated to be ~13 kJ mol<sup>-1</sup> for **p-H[4]R** and **t-H[4]R** with respect to  $[1\cdot H_2]^{4+}$  and  $[1\cdot H_2\subset(21C6)_2]^{4+}$ .

**Table S5.** Half-wave potentials ( $E_{1/2}$ ) of the redox pairs for the thread molecule and the assembled MIMs (vs Fc/Fc<sup>+</sup>).

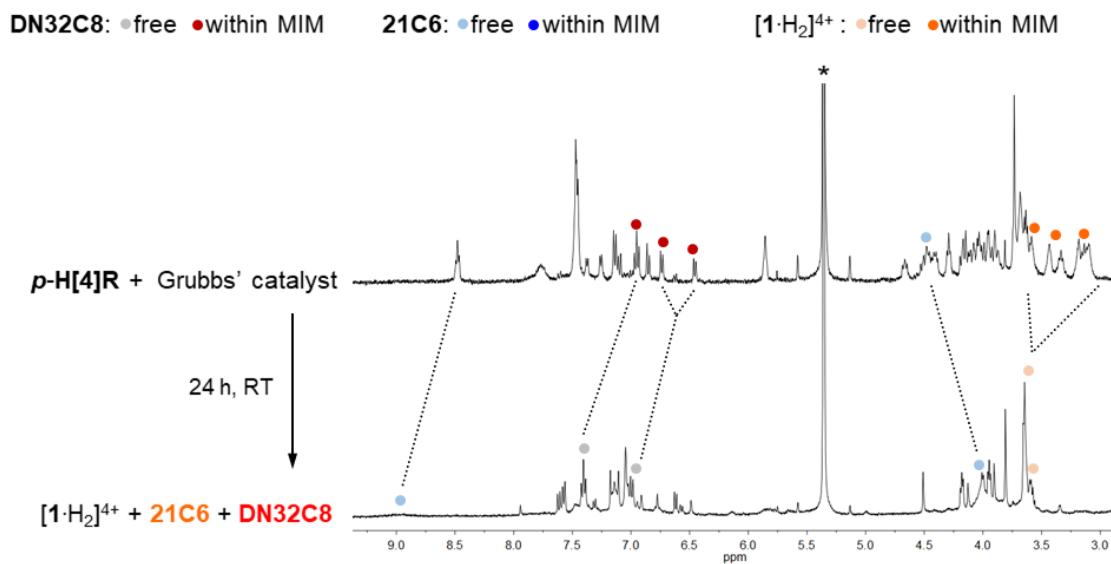

System	$E^1_{1/2}$ (1 <sup>st</sup> reduction) / V	$E^2_{1/2}$ (2 <sup>nd</sup> reduction) / V
[1·H <sub>2</sub> ] <sup>4+</sup>	-0.86	-1.30
[1·H <sub>2</sub> ⊂(21C6) <sub>2</sub> ] <sup>4+</sup>	-0.86	-1.36
<i>p</i> -H[4]R	-1.00	-1.46
<i>t</i> -H[4]R	-0.99	-1.43

## Rotaxane (*p*-H[4]R) degradation *via* ring-opening metathesis

**Scheme S6.** Degradation of rotaxane *p*-H[4]R *via* ring-opening metathesis.

Disassembly of the permanently protected rotaxane, *p*-H[4]R, was assessed by ring-opening metathesis (Scheme S6). A solution of *p*-H[4]R (2 mM) in  $\text{CD}_2\text{Cl}_2$  was mixed with Grubbs' II catalyst under  $\text{N}_2$  atmosphere and kept at RT for 24 h. The sample was analysed by  $^1\text{H}$  NMR spectroscopy within this period. The results (Figure S21) suggest full disassembly of the MIM, releasing the protecting unit and the viologen-based thread component into solution.

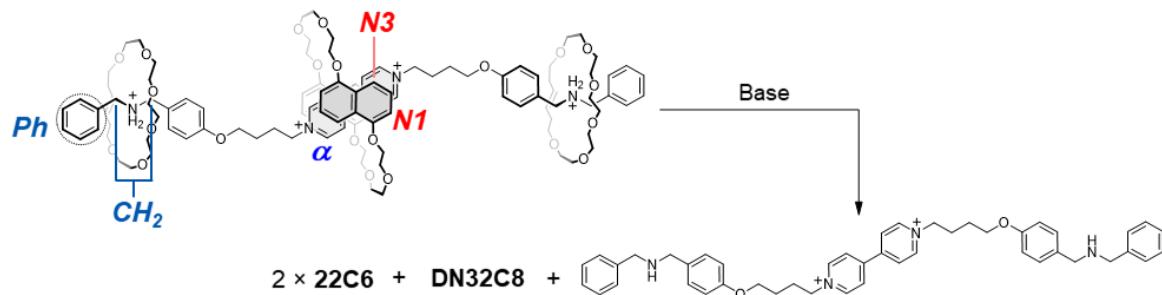

**Figure S21.** Partial  $^1\text{H}$  NMR spectra (400 MHz,  $\text{CD}_2\text{Cl}_2$ ) for the degradation of *p*-H[4]R through ring-opening metathesis. Diagnostic signals have been labeled. Broadening of the viologen resonances at  $\delta \approx 9$  ppm, suggest that the released axle and DN32C8 might undergo pseudorotaxane formation in solution after ring-opening.

## Unstoppering process on **t**-H[4]R

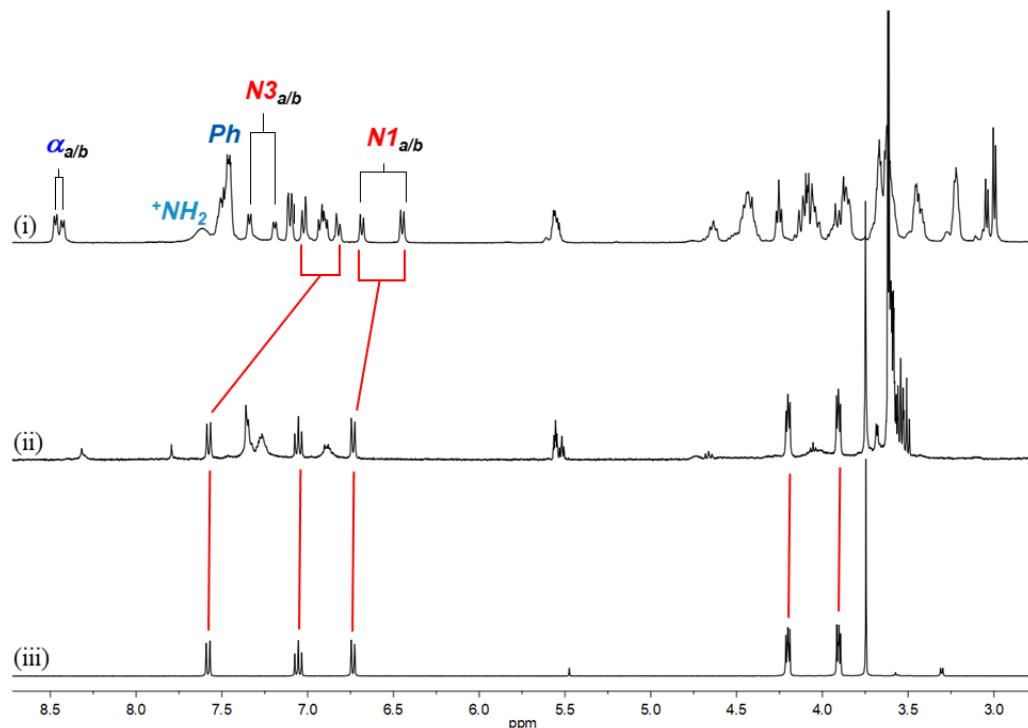

Solutions of rotaxane **t**-H[4]R at  $1 \times 10^{-3}$  M concentration were analyzed towards three different stimuli: base, polarity, and heat.

### Base trigger

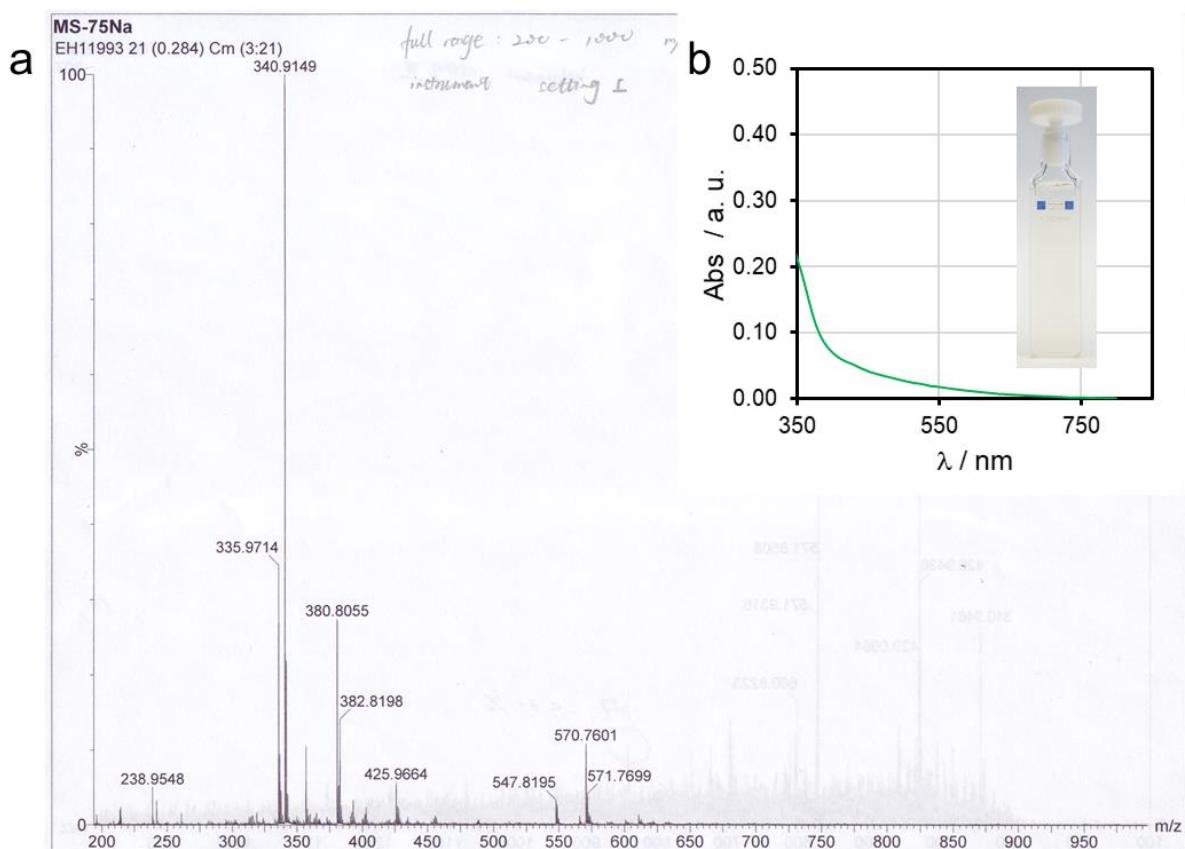

**Scheme S7.** Unstoppering process on **t**-H[4]R triggered by base addition.

A base solution (1 M,  $\text{NaOH}_{(\text{aq})}$ , 1 equiv) was added to a  $\text{CD}_3\text{CN}$  solution of **t**-H[4]R and stirred for 10 min at room temperature, then a  $^1\text{H}$  NMR spectrum was collected (Figure S22).

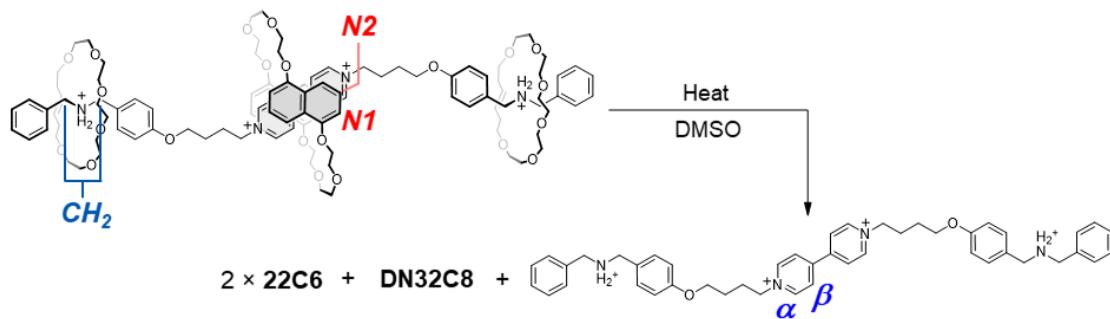

**Figure S22.** Partial  $^1\text{H}$  NMR spectra (400 MHz,  $\text{CD}_3\text{CN}$ ) of **t**-H[4]R (i) before and (ii) after the addition of one equiv of base ( $\text{NaOH}_{(\text{aq})}$ ), and (iii) pure **DN32C8**.

Based on the chemical shifts and the number of observable resonances, it is clear that the three free macrocycles were deposited in solution after deprotonation of the ammonium stations. The parent ions  $[\text{DN32C8} + \text{Na}]^+$  and  $[\text{22C6} + \text{Na}]^+$  were detected by HRMS at  $m/z$  570.7601 and 340.9149, respectively, while the ion  $[\text{1} + \text{DN32C8} + (2 \times \text{21C6}) + (2 \times \text{PF}_6) + 2\text{H}]^{2+}$  at  $m/z$  1085.0029, observed in Figure S66, was no longer identified in the spectrum (Figure S23a). In addition, just after mixing with base, the solution turned from red to pale yellow and the charge transfer band (490 nm) in the UV-vis spectrum was no longer detected (Figure S23b), suggesting that **t-H[4]R** was successfully disassembled.

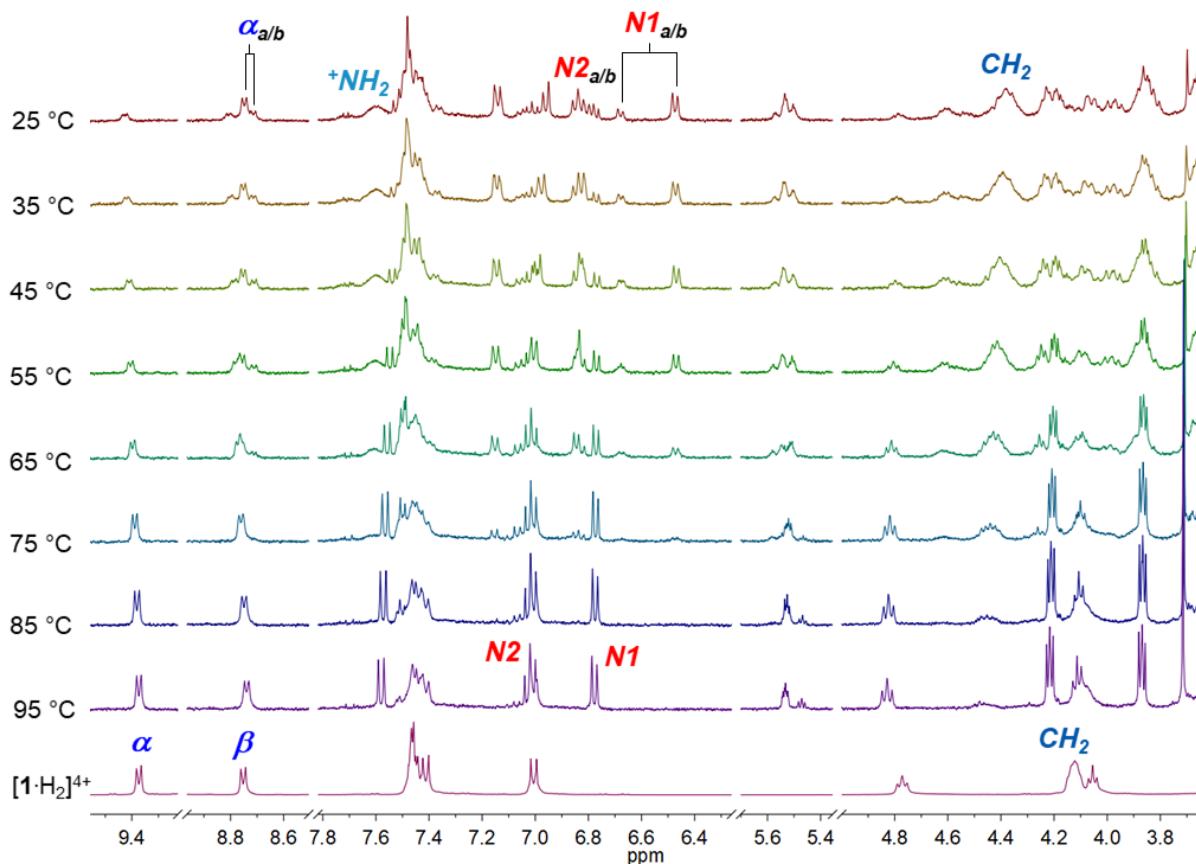

**Figure S23.** a) HRMS of **t-H[4]R** after the addition of one equiv of base ( $\text{NaOH}_{(\text{aq})}$ ). b) UV-vis spectrum (MeCN) of the disassembled system upon addition of base. The photograph shows the analyzed sample.

## Polarity and temperature stimuli

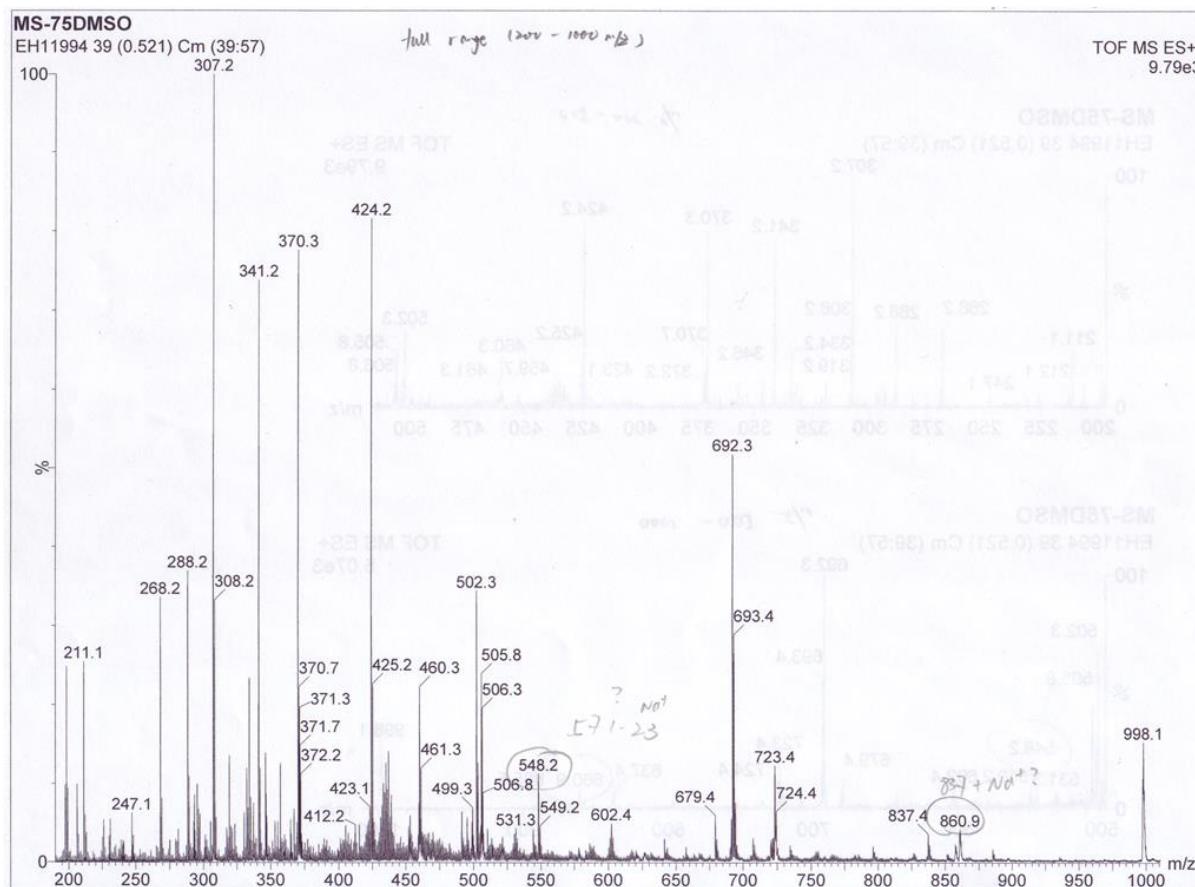

**Scheme S8.** [4]Rotaxane disassembly triggered by heat and polarity.

In contrast to other non-competitive solvents, such as  $\text{CH}_2\text{Cl}_2$  or  $\text{MeCN}$ ,  $\text{DMSO}$  produced unstopping at room temperature, releasing the protecting macrocycle **DN32C8**. Heating the system causes fast unstopping that renders all free components in solution, as clearly detected by  $^1\text{H}$  NMR spectroscopy (Figure S24).

**Figure S24.** Partial  $^1\text{H}$  NMR spectra (400 MHz,  $\text{CD}_3\text{CN}$ ) tracking the unstopping of  $t\text{-H}[4]\text{R}$  directed by two combined stimuli (polarity and heat).

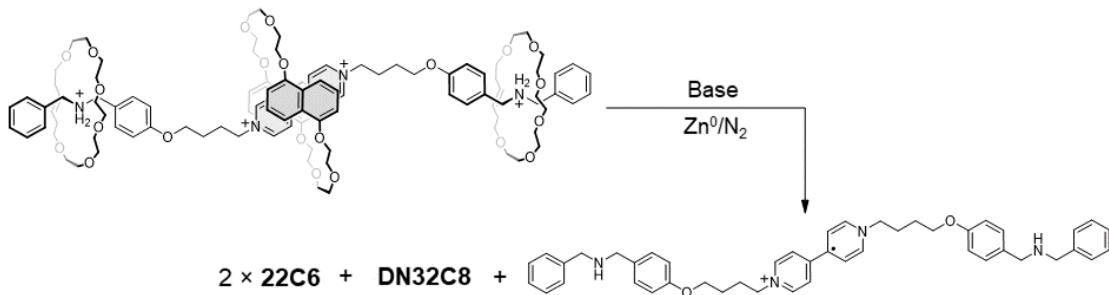

In addition, HRMS proved the presence of  $[\text{DN32C8} + \text{H}]^+$  at  $m/z$  548.2,  $[\mathbf{1} + \text{PF}_6]^+$  at  $m/z$  837.9, and  $[\mathbf{22C6} + \text{Na}]^+$  at  $m/z$  341.2, generated after the unstopping process, whereas the ion  $[\mathbf{1} + \text{DN32C8} + (2 \times \mathbf{22C6}) + (2 \times \text{PF}_6) + 2\text{H}]^{2+}$ , observed at  $m/z$  1085.0029 in Figure S66, was no longer detected (Figure S25).

**Figure S25.** HRMS for rotaxane **t-H[4]R** after heating in DMSO at 90 °C.

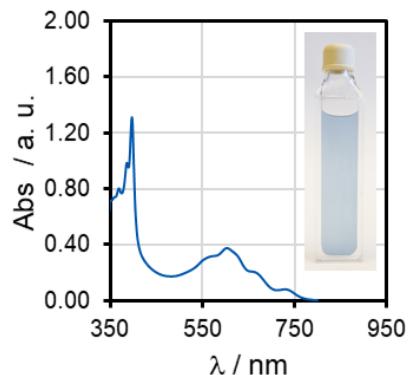

## Controlled deprotection of **t**-**H[4]R**

### Base trigger

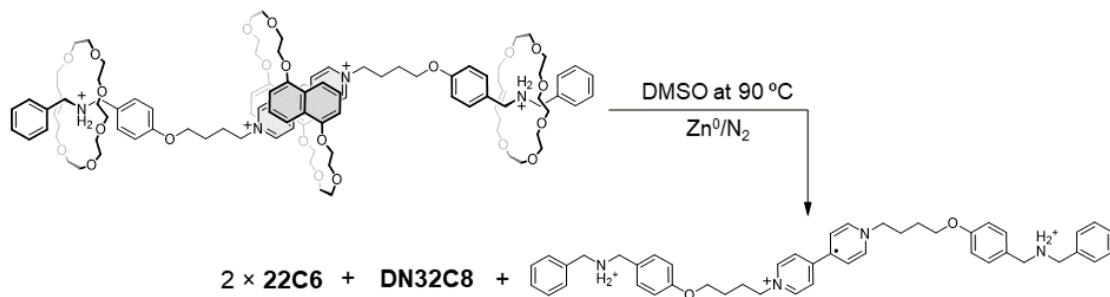

**Scheme S9.** Controlled deprotection through base trigger.

A suspension containing **t**-**H[4]R** (1 mL,  $2 \times 10^{-3}$  M in CH<sub>3</sub>CN) and zinc dust (50 mg) was treated with one equiv of base (1 M NaOH<sub>(aq)</sub>) under a N<sub>2</sub> atmosphere; an immediate change of color from red to blue due to the formation of [1·H<sub>2</sub>]<sup>(3+)\*</sup> was noticed; this is a consequence of the unstopping/deprotection sequence. Figure S26 shows the UV-vis spectrum of the system after deprotection, this experiment matches with the one reported for species [1·H<sub>2</sub>]<sup>(3+)\*</sup>, shown in Figure S2a.

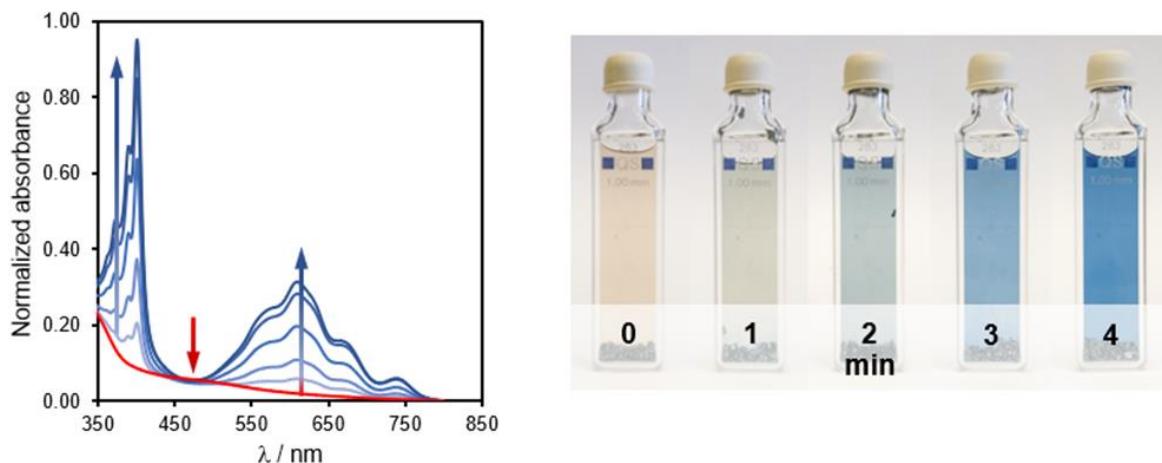

**Figure S26.** UV-vis spectrum (MeCN) of **t**-**H[4]R** after the unstopping/deprotection process. The photograph shows the prepared sample.

## Polarity and temperature effect

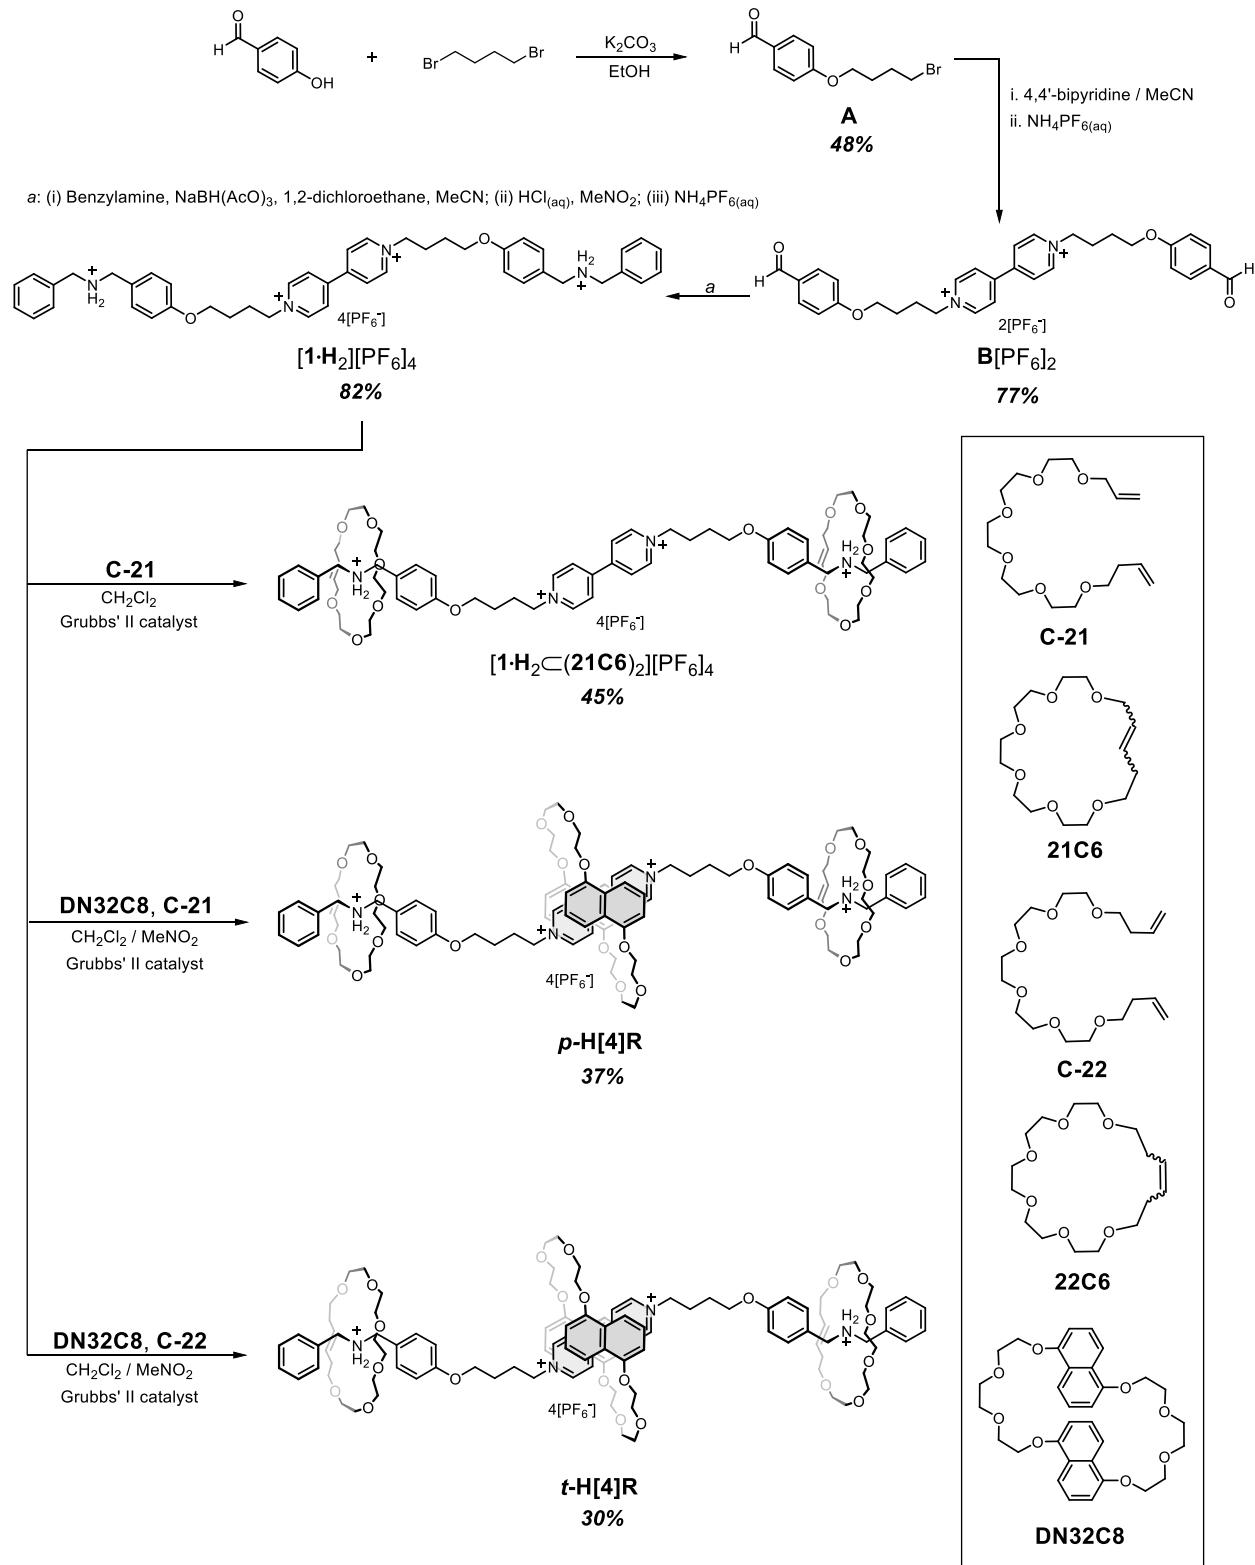

**Scheme S10.** Controlled deprotection via polarity and thermal stimuli.

A solution of **t-H[4]R** (400  $\mu\text{L}$ ,  $1 \times 10^{-3}$  M) was prepared in deaerated DMSO, then loaded with zinc dust (10 mg) and heated at  $90^\circ\text{C}$ . UV-vis spectra were collected every minute followed by equilibration to RT. Figure S27 shows the collected spectra along with photographs of the samples. The registered bands in the spectra corroborate the gradual formation of  $[\mathbf{1}\cdot\text{H}_2]^{(3+)*}$ , which is produced by the thermal-triggered deprotection process.

**Figure S27.** UV-VIS spectra for the gradual deprotection of **t-H[4]R** via thermal/polarity effect. Photographs show the gradual deprotection observed at macroscopic level.

## Synthesis

**Scheme S11.** Synthesis of the targeted hetero[4]rotaxanes and their precursors.

## Functionalized benzaldehyde A

The synthesis was adapted from a reported method.<sup>10</sup> 1,4-Dibromobutane (14.6 g, 66.7 mmol) and 4-hydroxybenzaldehyde (2.0 g, 16.7 mmol) were dissolved in EtOH (60 mL), and K<sub>2</sub>CO<sub>3</sub> (4.6 g, 33.3 mmol) was then added in one portion; the resulting suspension was heated under reflux and stirred for 10 h. After cooling to room temperature, the mixture was filtered, and the filtrate evaporated under vacuum. Column chromatography (SiO<sub>2</sub>, petroleum ether:DCM, 1:1, *R*<sub>f</sub> = 0.49) afforded compound **A** as a yellow oil (2.1 g, 8.2 mmol, 48% yield); this compound crystallizes over time. <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ<sub>H</sub> 9.86 (s, 1H), 7.86 (d, *J* = 8.7 Hz, 2H), 7.12 (d, *J* = 8.7 Hz, 2H), 4.13 (t, *J* = 6.2 Hz, 2H), 3.61 (t, *J* = 6.6 Hz, 2H), 2.11–1.74 (m, 4H); <sup>13</sup>C NMR (100 MHz, DMSO-*d*<sub>6</sub>) δ<sub>C</sub> 191.8, 164.0, 132.3, 130.1, 115.4, 67.7, 35.2, 29.4, 27.7; ESI-HRMS, *m/z* for [A + H]<sup>+</sup> 257.0176 (found), 257.0177 (calculated), relative error -0.4 ppm.

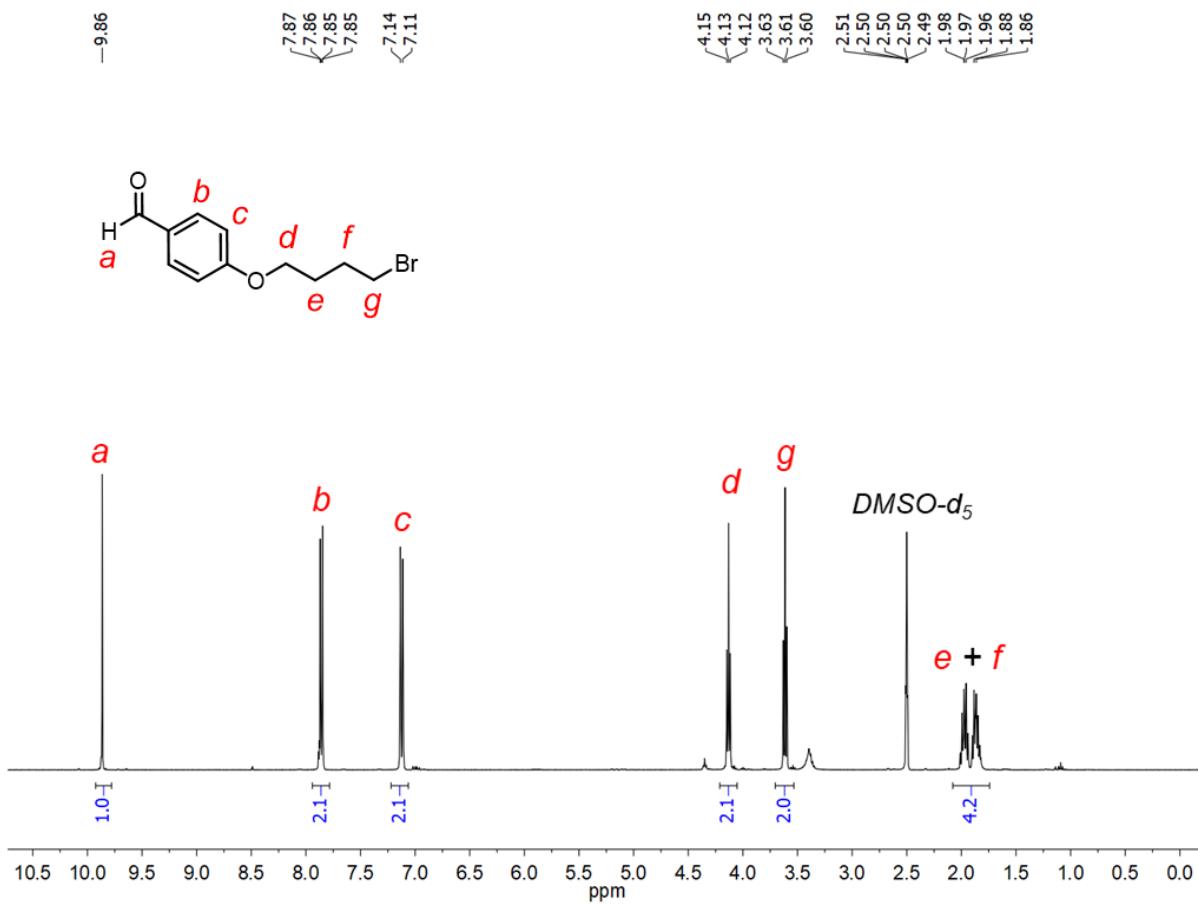

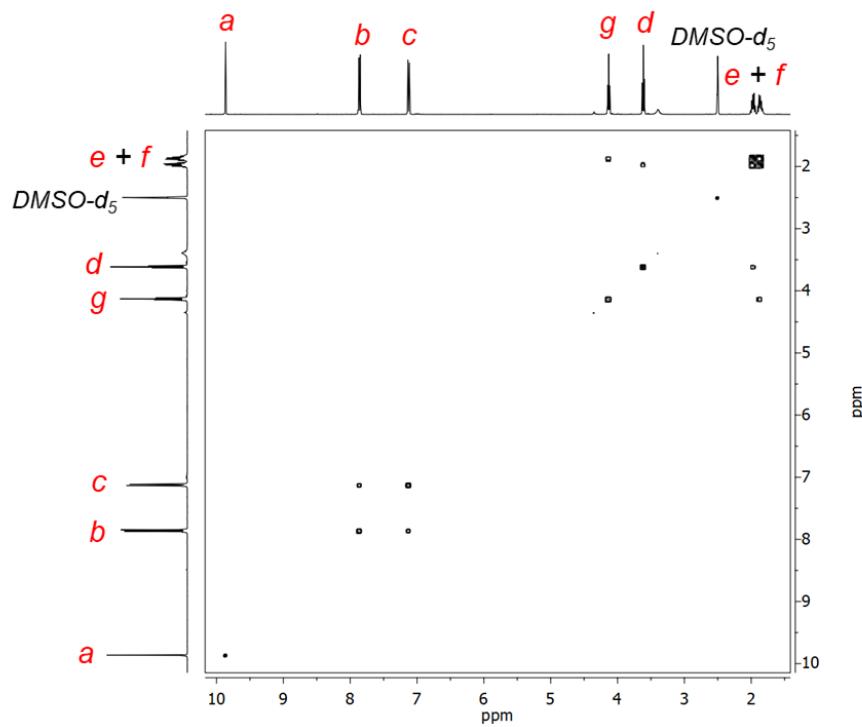

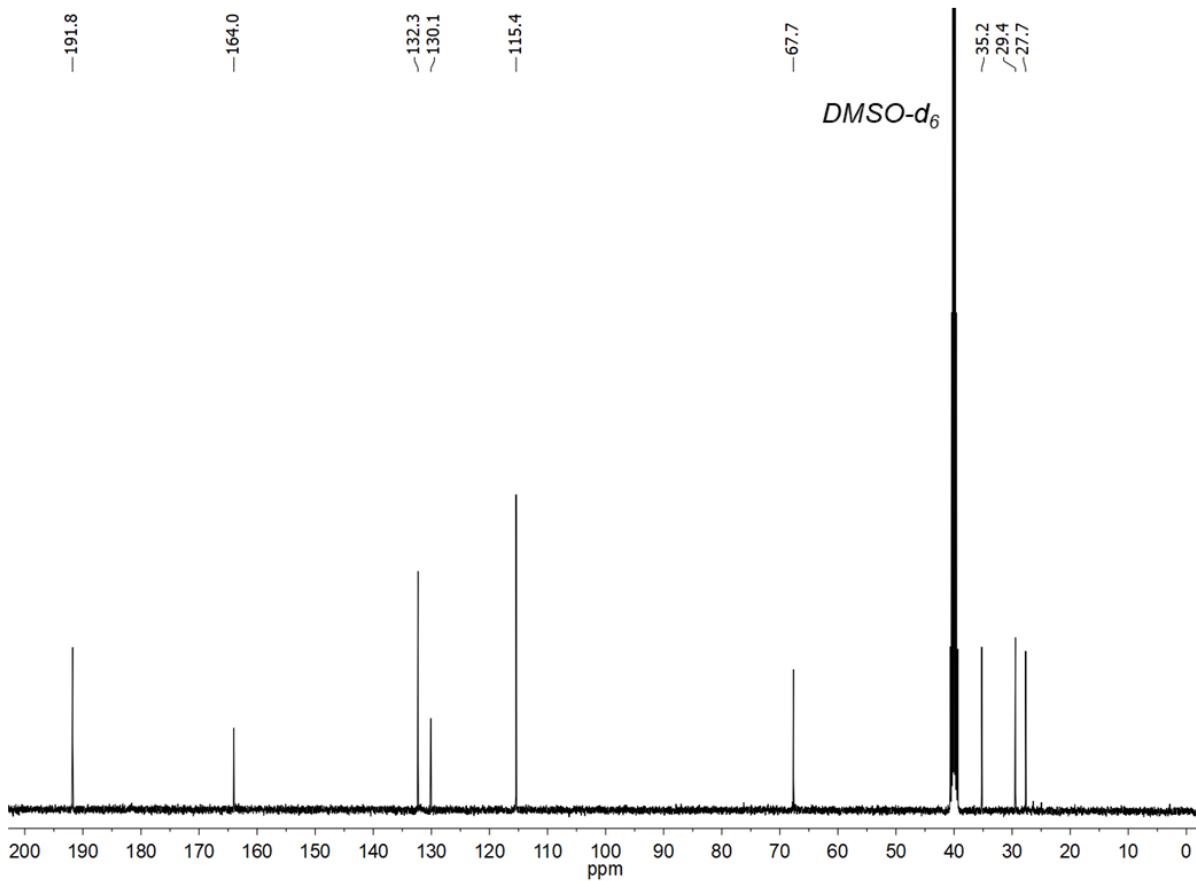

Figure S28. <sup>1</sup>H NMR spectrum (400 MHz, DMSO-*d*<sub>6</sub>) of compound **A**.

**Figure S29.**  $^1\text{H}$ - $^1\text{H}$  COSY NMR spectrum (400 MHz,  $\text{DMSO}-d_6$ ) of compound **A**.

**Figure S30.**  $^{13}\text{C}$   $\{{}^1\text{H}\}$  NMR spectrum (100 MHz,  $\text{DMSO}-d_6$ ) of precursor **A**.

## 4,4'-Bipyridinium salt B[PF<sub>6</sub>]<sub>2</sub>

A solution of precursor **A** (866.0 mg, 3.38 mmol) and 4,4'-bipyridine (134.5 mg, 0.84 mmol) in MeCN (3 mL) was heated under reflux for 4 d and then cooled to room temperature. Separating the precipitate by filtration allowed isolation of **BBr**<sub>2</sub> as a yellow solid, which was washed with MeCN (30 mL) and CHCl<sub>3</sub> (30 mL) and dissolved in H<sub>2</sub>O (20 mL). The addition of NH<sub>4</sub>PF<sub>6</sub> (522.0 mg, 3.20 mmol) in one portion caused precipitation of a white solid, which was isolated on a Buchner funnel, washed with H<sub>2</sub>O (50 mL) and cold MeOH (30 mL), and air-dried to isolate **B[PF<sub>6</sub>]<sub>2</sub>**. <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>)  $\delta$ <sub>H</sub> 9.86 (s, 2H), 9.46 (d, *J* = 5.8 Hz, 4H), 8.82 (d, *J* = 6.0 Hz, 4H), 7.87 (d, *J* = 8.7 Hz, 4H), 7.12 (d, *J* = 8.7 Hz, 4H), 4.80 (t, *J* = 7.1 Hz, 4H), 4.17 (t, *J* = 6.2 Hz, 4H), 2.18 (m, 4H), 1.83 (m, 4H); <sup>13</sup>C NMR (100 MHz, DMSO-*d*<sub>6</sub>)  $\delta$ <sub>C</sub> 191.8, 163.9, 149.0, 146.3, 132.3, 130.1, 127.1, 115.4, 67.8, 61.0, 28.1, 25.6. ESI-HRMS, *m/z* for [B]<sup>2+</sup> 255.1254 (found), 255.1259 (calculated), relative error -2.0 ppm.

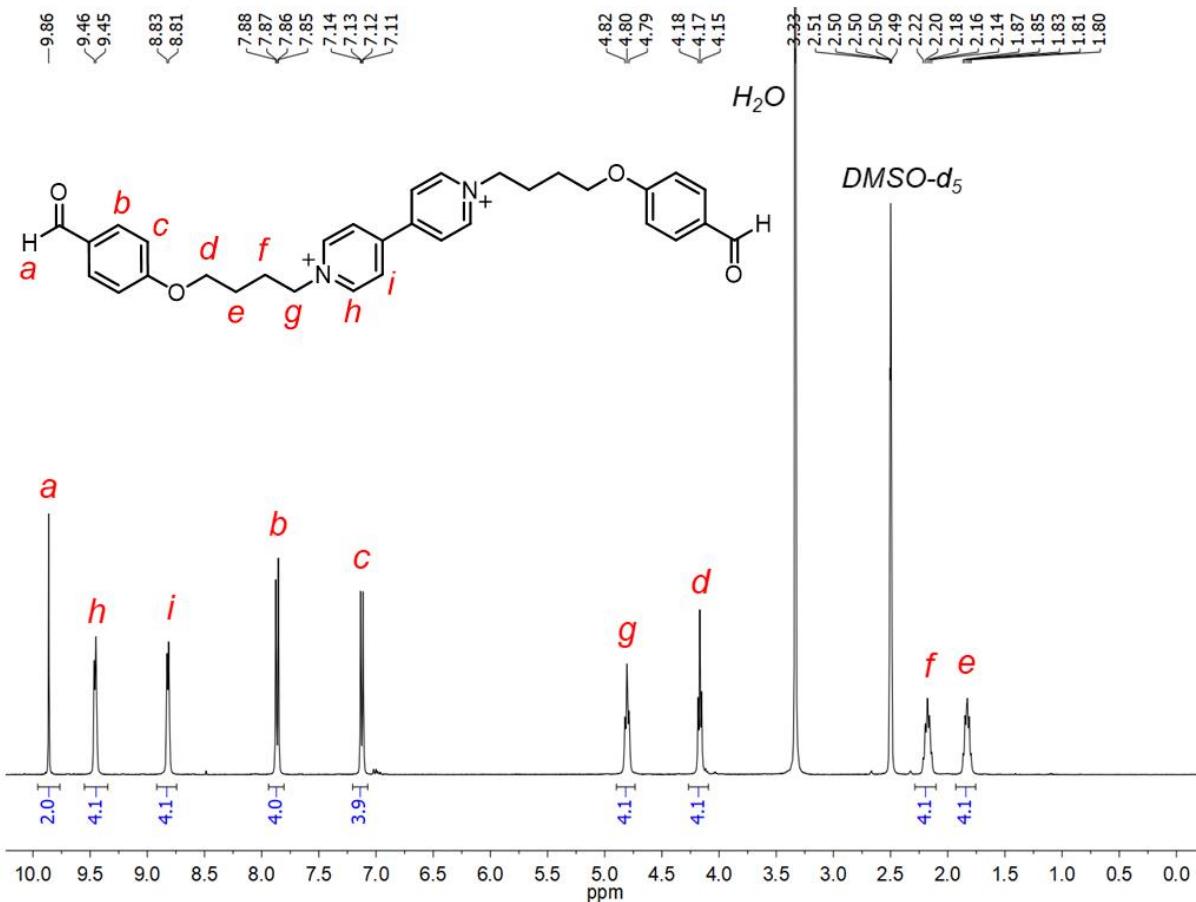

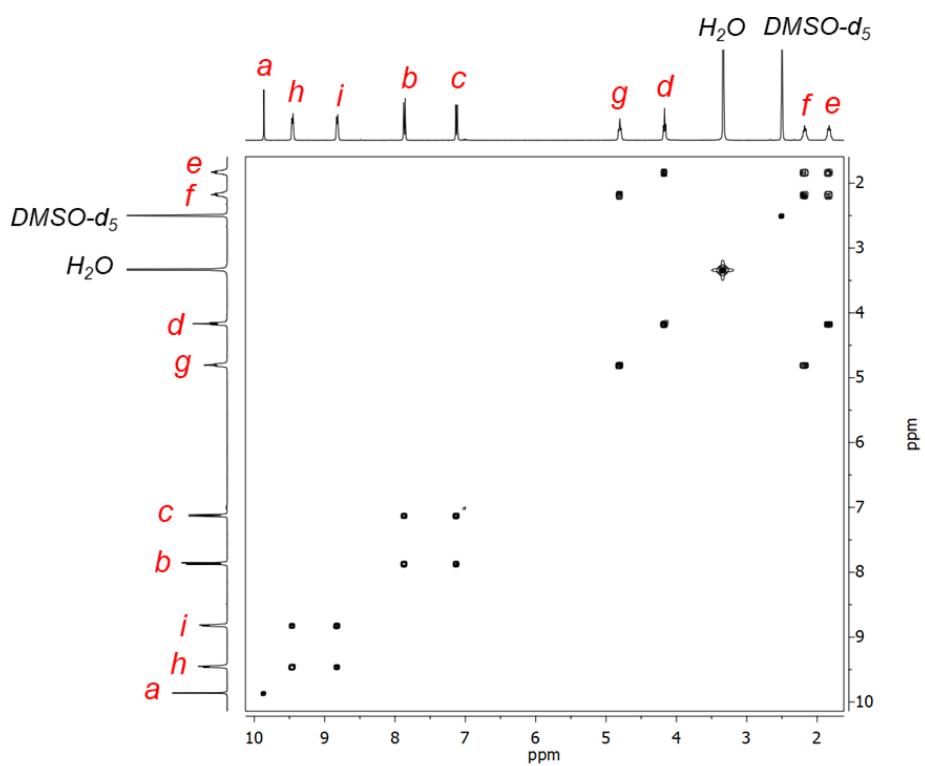

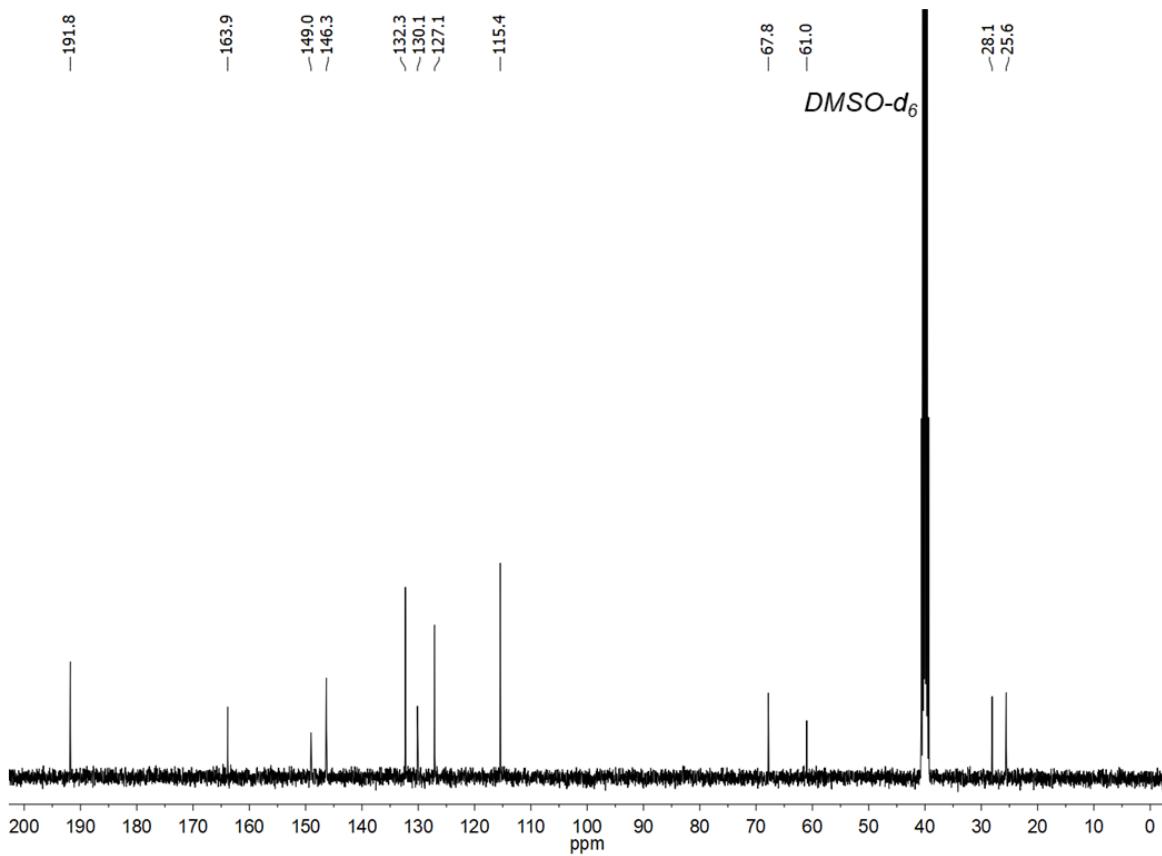

Figure S31. <sup>1</sup>H NMR spectrum (400 MHz, DMSO-*d*<sub>6</sub>) of salt **B[PF<sub>6</sub>]<sub>2</sub>**.

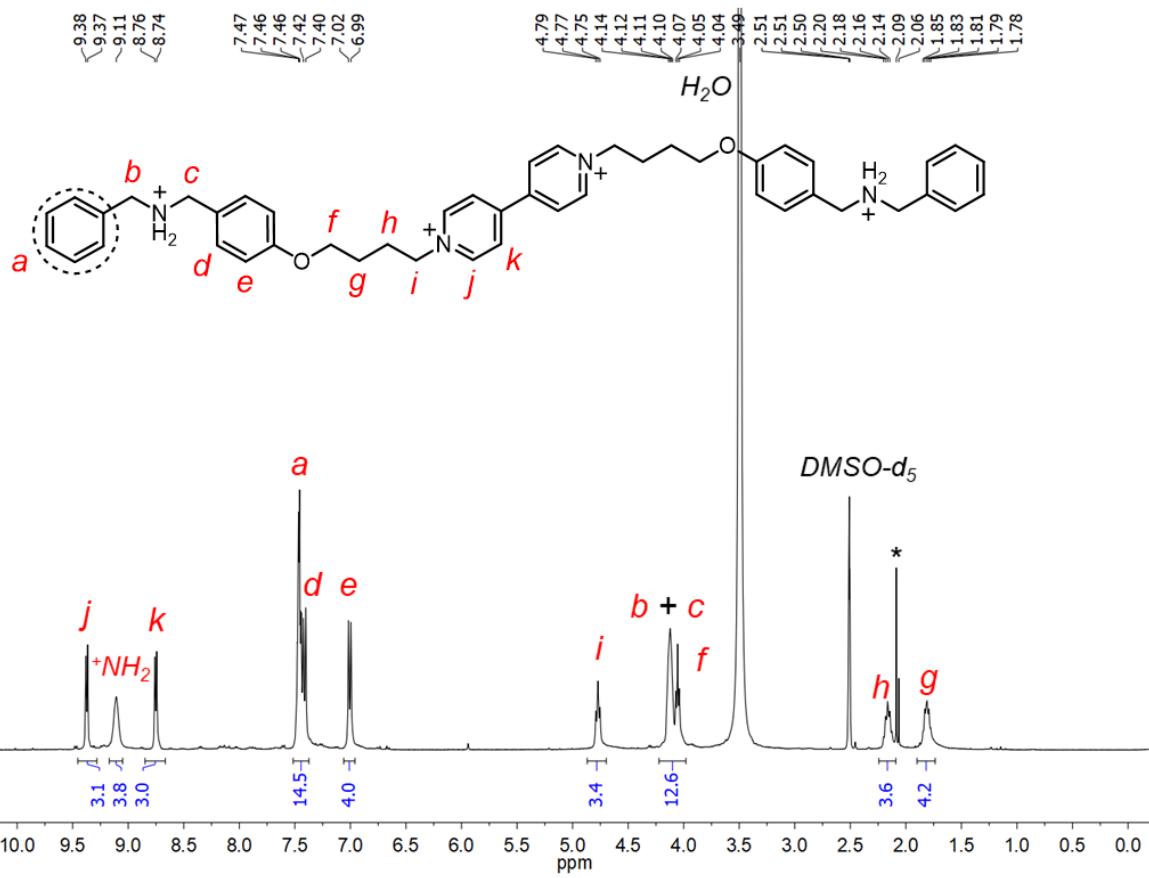

**Figure S32.**  $^1\text{H}$ - $^1\text{H}$  COSY NMR spectrum (400 MHz,  $\text{DMSO}-d_6$ ) of compound  $\mathbf{B}[\text{PF}_6]_2$ .

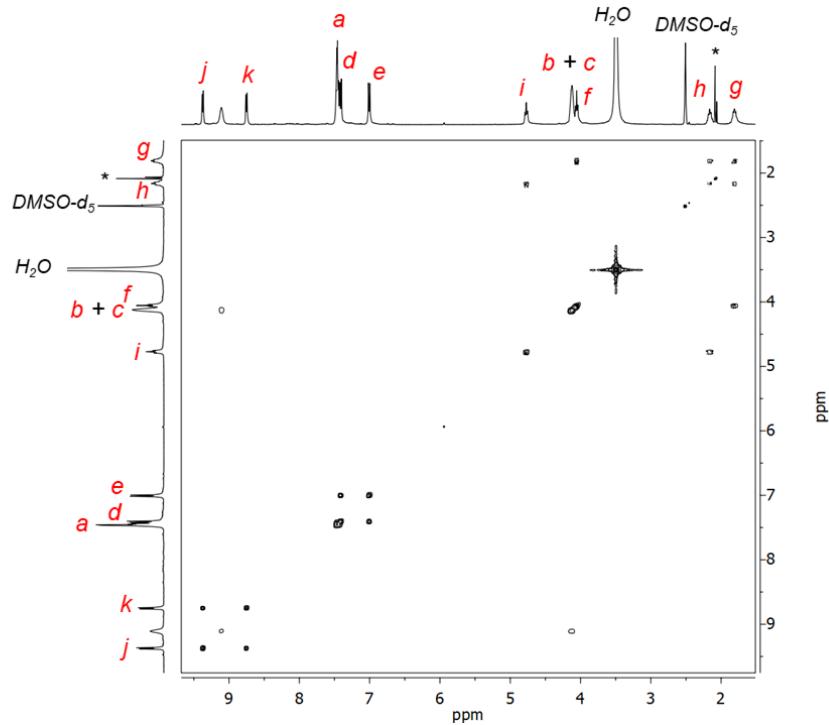

**Figure S33.**  $^{13}\text{C}$   $\{^1\text{H}\}$  NMR spectrum (100 MHz,  $\text{DMSO}-d_6$ ) of precursor  $\mathbf{B}[\text{PF}_6]_2$ .

### Thread [1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>

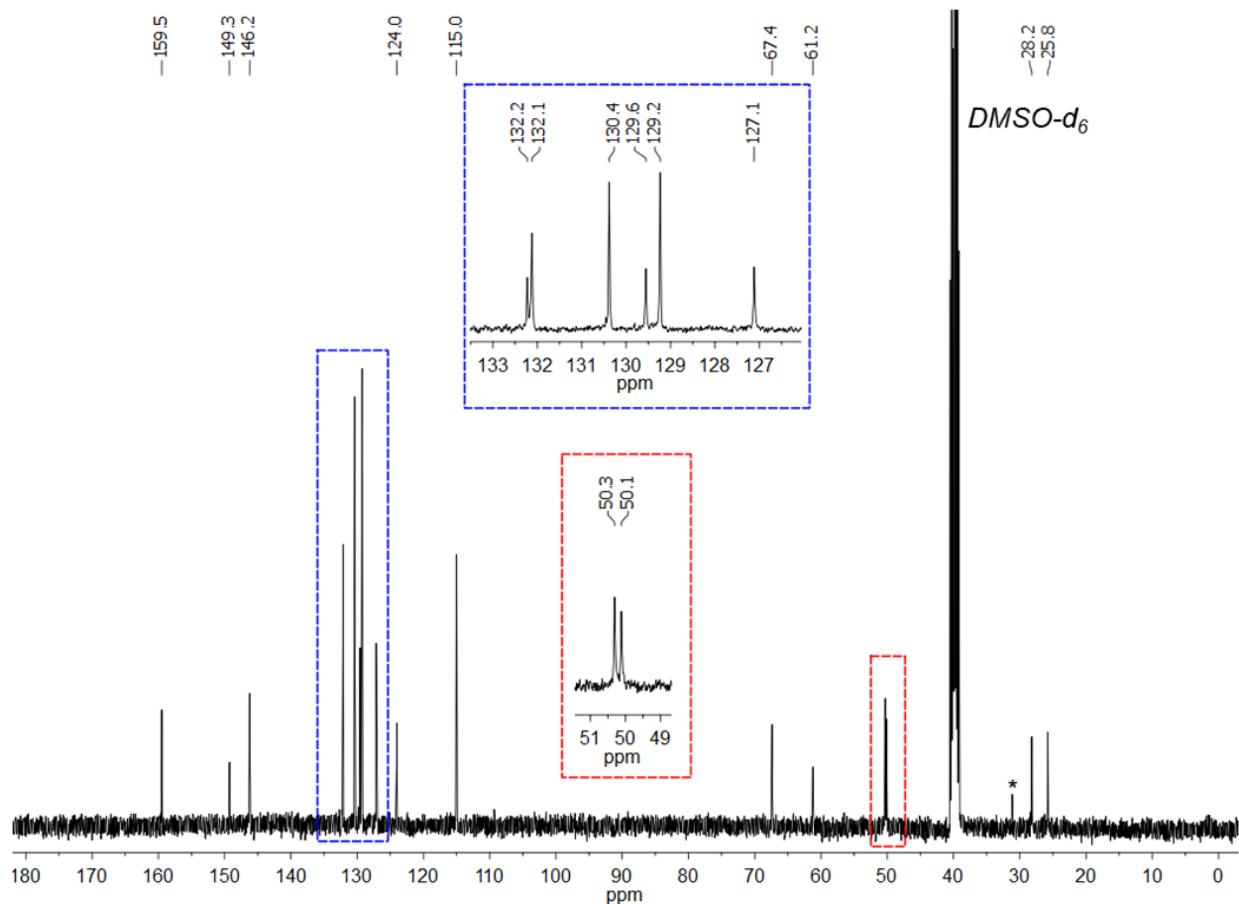

Precursor **B**[PF<sub>6</sub>]<sub>2</sub> (1.0 g, 1.25 mmol) and benzylamine (297.5 mg, 2.75 mmol) were dissolved in MeCN (12.5 mL) and 1,2-dichloroethane (5 mL), followed by the addition of NaBH(OAc)<sub>3</sub> (831.3 mg, 3.90 mmol). The resulting suspension was stirred for 16 h at room temperature and an extra portion of NaBH(OAc)<sub>3</sub> was added (415.7 mg, 1.95 mmol). After stirring the mixture for 16 h more, it was quenched with saturated NaHCO<sub>3(aq)</sub> (50 mL) and the organic layer was separated. The aqueous layer was extracted with MeNO<sub>2</sub> (3 × 15 mL) and all combined organic phases were dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated under reduced pressure. The brown residue was then dissolved in MeNO<sub>2</sub> (5 mL) and 12 M aqueous HCl (990 μL) was added dropwise as the residue was rapidly stirred. After 10 min of continuous stirring, a solution of NH<sub>4</sub>PF<sub>6</sub> (1.0 g, 6.3 mmol) in H<sub>2</sub>O (15 mL) was added. Finally, the organic phase was separated, washed with H<sub>2</sub>O (3 × 25 mL) and dried (Na<sub>2</sub>SO<sub>4</sub>). Rotary evaporation yielded salt [1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub> as a brown crystalline solid (1.3 g, 1.02 mmol, 82% yield). <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ<sub>H</sub> 9.37 (d, *J* = 6.9 Hz, 4H), 9.11 (br, 4H), 8.75 (d, *J* = 7.0 Hz, 4H), 7.68–7.30 (m, 10H), 7.41 (d, *J* = 8.7 Hz, 4H), 7.01 (d, *J* = 8.7 Hz, 4H), 4.77 (t, *J* = 7.4 Hz, 4H), 4.12 (br, 8H), 4.05 (t, *J* = 6.2 Hz, 4H), 2.17 (m, 4H), 1.82 (m, 4H); <sup>13</sup>C NMR (100 MHz, DMSO-*d*<sub>6</sub>) δ<sub>C</sub> 159.5, 149.3, 146.2, 132.2, 132.1, 130.4, 129.6, 129.2, 127.1, 124.0, 115.0, 67.4, 61.2, 50.3, 50.1, 28.2, 25.8. ESI-HRMS, *m/z* for [1 + PF<sub>6</sub>]<sup>+</sup> 837.3728 (found), 837.3732 (calculated), relative error -0.5 ppm.

**Figure S34.**  $^1\text{H}$  NMR spectrum (400 MHz,  $\text{DMSO}-d_6$ ) of compound  $[1 \cdot \text{H}_2][\text{PF}_6]_4$ . \* Denotes  $\text{CH}_3\text{CN}$  and  $(\text{CH}_3)_2\text{CO}$ .

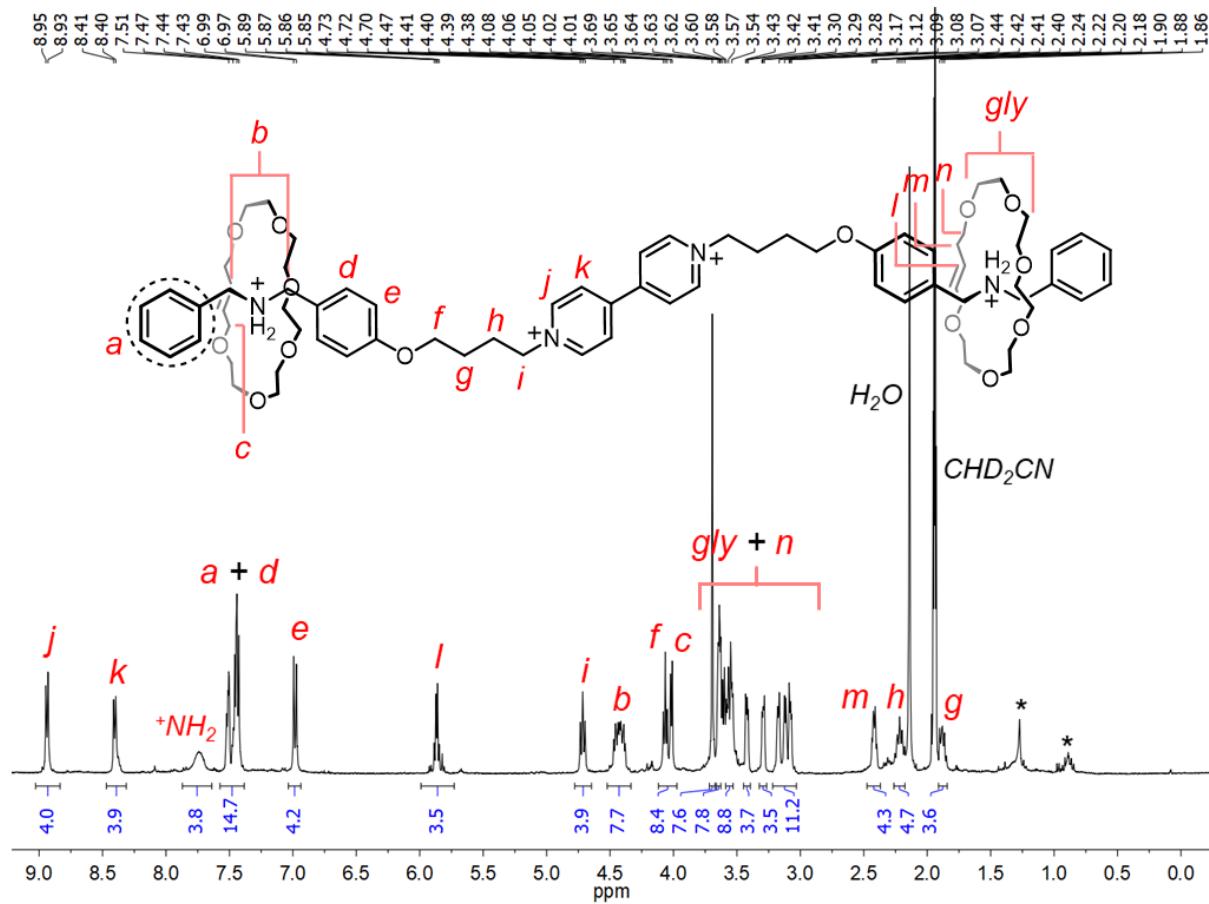

**Figure S36.**  $^{13}\text{C}$  { $^1\text{H}$ } NMR spectrum (100 MHz,  $\text{DMSO}-d_6$ ) of compound  $[1 \cdot \text{H}_2][\text{PF}_6]_4$ . \* Denotes  $(\text{CH}_3)_2\text{CO}$ .

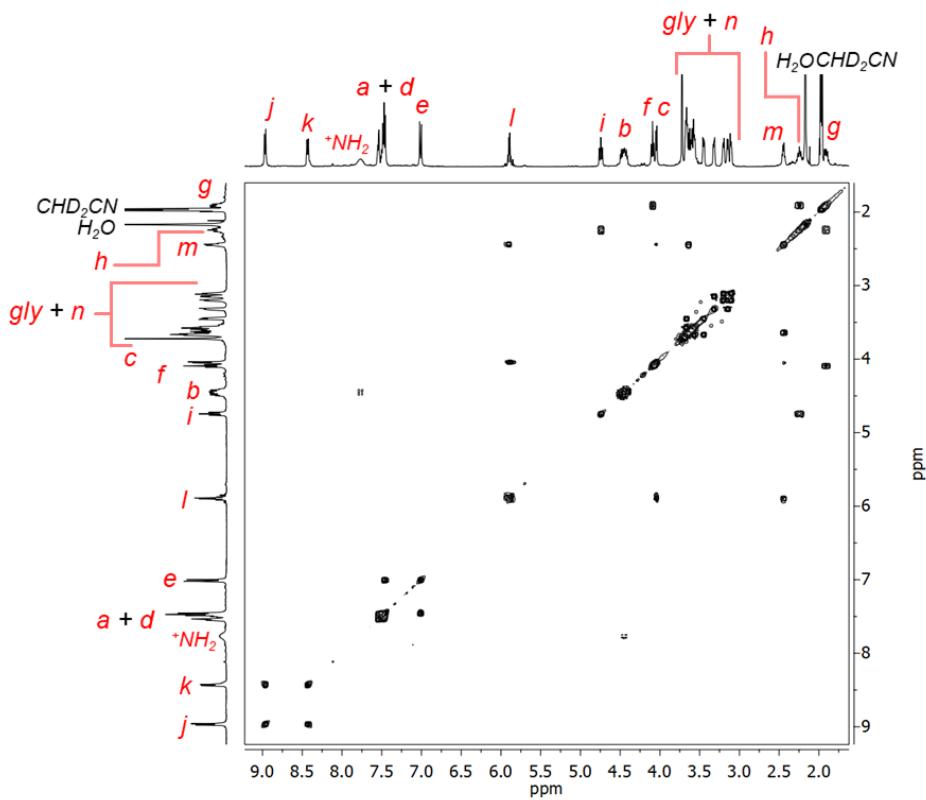

### [3]Rotaxane $[1 \cdot \text{H}_2 \subset (\text{21C6})_2][\text{PF}_6]_4$

A solution of **C-21** (159.5 mg, 0.48 mmol) and  $[1 \cdot \text{H}_2][\text{PF}_6]_4$  (150.0 mg, 0.12 mmol), prepared in dry DCM (40 mL) and dry  $\text{MeNO}_2$  (5 mL), was stirred for 15 min at room temperature under a  $\text{N}_2$  atmosphere. Then, second-generation Grubbs' catalyst (29.5 mg, 0.048 mmol) was added and the resulting mixture was stirred for 15 min under same conditions, followed by 24 h of heating at 43 °C. After cooling the system to room temperature, ethyl vinyl ether was added (5 mL) and the mixture was stirred for 20 min followed by evaporation under reduced pressure. Column chromatography ( $\text{SiO}_2$ ,  $\text{MeOH}:\text{DCM}$ , 2.5:7.5,  $R_f = 0.2$ ) afforded rotaxane  $[1 \cdot \text{H}_2 \subset (\text{21C6})_2][\text{PF}_6]_4$  as a pale yellow solid (101.7 mg, 0.05 mmol, 45% yield).  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_3\text{CN}$ )  $\delta_{\text{H}}$  8.94 (d,  $J = 6.8$  Hz, 4H), 8.40 (d,  $J = 6.7$  Hz, 4H), 7.74 (br, 4H), 7.58–7.36 (m, 14H), 6.98 (d,  $J = 8.7$  Hz, 4H), 5.99–5.74 (m, 4H), 4.72 (t,  $J = 7.6$  Hz, 4H), 4.54–4.32 (m, 8H), 4.06 (t,  $J = 6.1$  Hz, 4H), 4.02 (d,  $J = 5.6$  Hz, 4H), 3.69 (s, 8H), 3.67–3.52 (m, 16H), 3.45–3.39 (m, 4H), 3.32–3.27 (m, 4H), 3.20–3.06

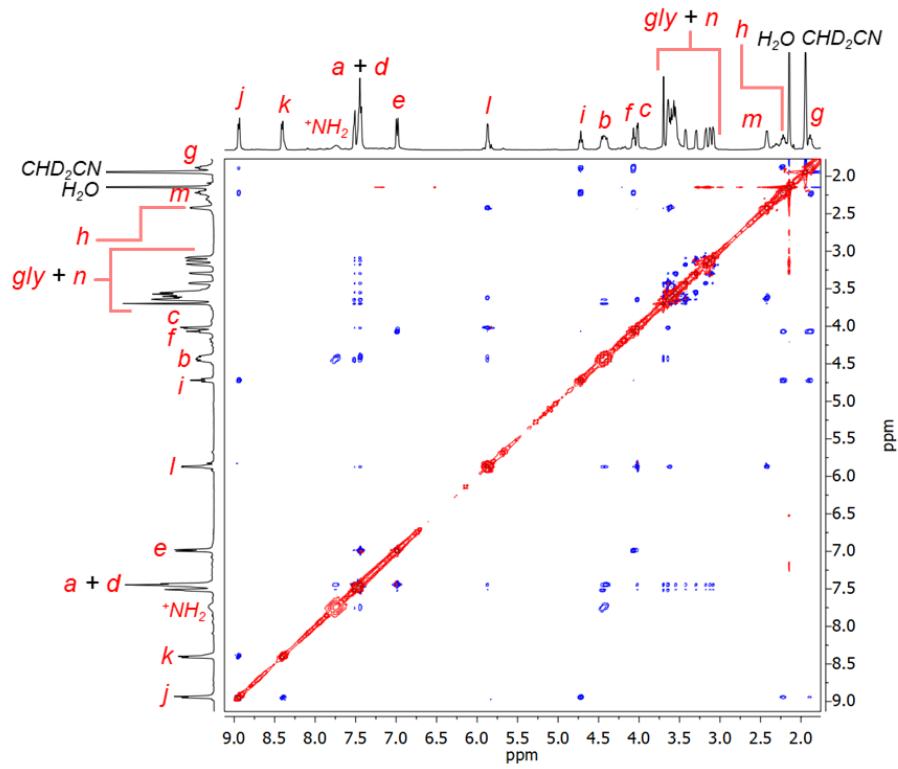

(m, 12H), 2.44–3.40 (m,  $J = 4.8$  Hz, 4H), 2.25–2.18 (m, 4H), 1.92–1.85 (m, 4H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CD}_3\text{CN}$ )  $\delta_{\text{C}}$  159.5, 150.1, 145.6, 136.8, 132.5, 132.0, 130.4, 129.2, 128.6, 127.8, 127.3, 124.7, 114.4, 72.2, 71.9, 71.6, 71.3, 71.1, 71.0, 70.5, 70.4, 70.3, 70.2, 70.0, 67.1, 61.9, 51.1, 50.7, 33.3, 28.0, 25.5. ESI-HRMS,  $m/z$  for  $[1 + (2 \times \mathbf{21C6}) + 2\text{H}]^{4+}$  325.7016 (found), 325.6999 (calculated), relative error 5.2 ppm.

## General synthesis of the hetero[4]rotaxane structures

Macrocycle **DN32C8**, salt **[1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>**, and the corresponding glycol precursor (**C-21** or **C-22**) were all dissolved in MeCN (1 mL) and DCM (9 mL). The resulting red solution was stirred for 15 min followed by rotary evaporation ( $T < 30$  °C) to dry the product. The residue was then dissolved under N<sub>2</sub> atmosphere in dry CH<sub>2</sub>Cl<sub>2</sub> (23 mL) and dry MeNO<sub>2</sub> (3 mL). After stirring for 5 min at room temperature, second-generation Grubbs' catalyst was added, and stirring was continued for 10 min. The reaction mixture was heated at 43 °C for 36 h and then cooled to room temperature to be subsequently quenched with ethyl vinyl ether (5 mL) and stirred for 20 min. After removing all solvents by rotary evaporation ( $T < 30$  °C) the hetero[4]rotaxane species, **p-H[4]R** and **t-H[4]R**, were purified by column chromatography (SiO<sub>2</sub>, MeOH:DCM, 2.5:7.5).

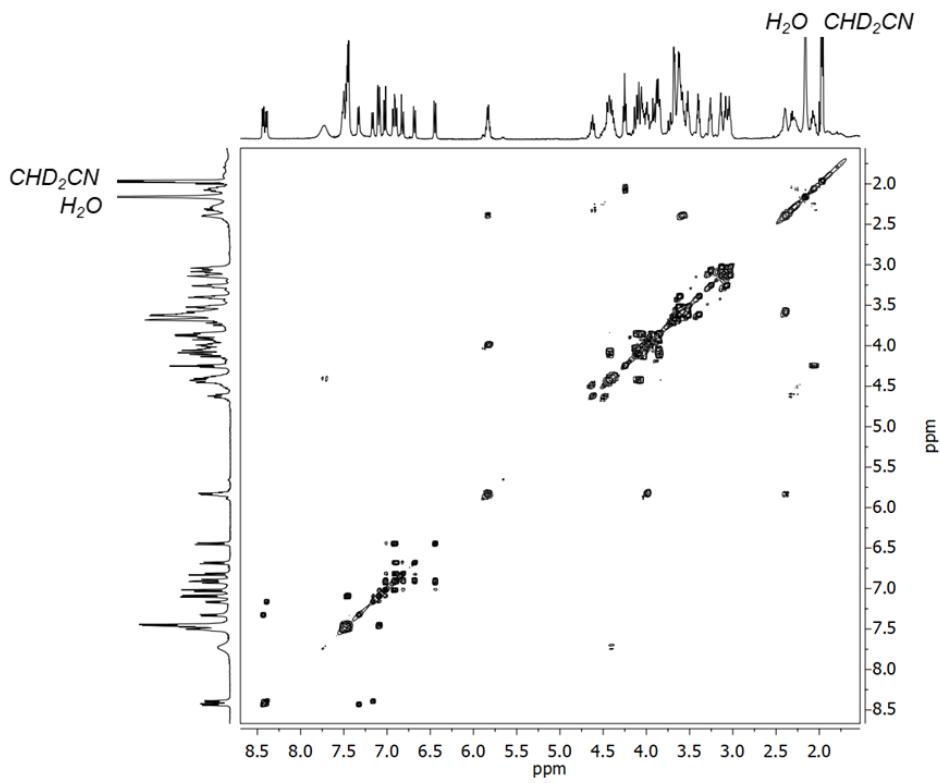

**p-H[4]R:** compound **C-21** (85.1 mg, 0.26 mmol); macrocycle **DN32C8** (131.6 mg, 0.24 mmol); salt **[1·H<sub>2</sub>][PF<sub>6</sub>]<sub>4</sub>** (80.0 mg, 0.06 mmol), Grubbs' catalyst (16.0 mg, 0.03 mmol).  $R_f = 0.24$ , red crystalline solid, 37% yield (43.8 mg, 0.02 mmol). <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>CN)  $\delta_{\text{H}}$  H<sub>j</sub> (4H) observed as H<sub>j/j'</sub> at 8.41 (d,  $J = 6.4$  Hz) and 8.37 (d,  $J = 6.4$  Hz), 7.70 (br, 4H), 7.50–7.40 (m, 14H), H<sub>k</sub> (4H) observed as H<sub>k/k'</sub> at 7.30 (d,  $J = 6.6$  Hz) and 7.14 (d,  $J = 6.4$  Hz), 7.07 (d,  $J = 6.8$  Hz, 4H), H<sub>o</sub> (4H) observed as H<sub>o/o'</sub> at 7.00 (d,  $J = 8.3$  Hz) and 6.79 (d,  $J = 8.3$  Hz), H<sub>p</sub> observed as H<sub>p/p'</sub> at 6.91–6.86 (m, 4H), H<sub>q</sub> (4H) observed as H<sub>q/q'</sub> at 6.66 (d,  $J = 7.5$  Hz) and 6.42 (d,  $J = 7.6$  Hz), 5.81–5.78 (m, 4H), H<sub>i</sub> (4H) observed as H<sub>i/i'</sub> at 4.59 (t,  $J = 7.7$  Hz) and 4.52–4.45 (br), 4.44–4.32 (m, 8H), 4.22 (t,  $J = 5.9$  Hz, 4H), 4.14–3.79 (m, 28H), 3.72–3.46 (m, 28H), 3.39–3.35 (m, 4H), 3.25–3.22 (m, 4H), 3.17–2.97 (m, 12H), 2.38–2.35 (m, 4H), 2.26 (br, 4H), 2.07–2.01 (m, 4H); <sup>13</sup>C NMR (100 MHz, CD<sub>3</sub>CN)  $\delta_{\text{C}}$  159.5, 153.3, 153.0, 144.1, 144.0, 143.9, 143.8, 136.7, 132.5, 132.1, 130.4, 129.1, 128.6, 127.7, 125.7, 125.5, 125.3, 124.71, 124.66, 124.4, 123.7, 114.4, 113.5, 105.3, 105.1, 72.1, 71.8, 71.6, 71.2, 71.1, 70.9, 70.7, 70.5, 70.4, 70.2, 70.1, 69.94, 69.91, 69.89, 67.8, 67.3, 67.2, 61.2, 51.0, 50.6, 33.3, 28.2, 28.1, 25.9. UV-vis (MeCN):  $\lambda_{\text{max}}$  ( $\varepsilon$ ) 475 nm (1520 mol<sup>-1</sup> dm<sup>3</sup> cm<sup>-1</sup>). ESI-HRMS, *m/z* for [1 + **DN32C8** + (2 × **21C6**) + 2H]<sup>4+</sup> 462.7604 (found), 462.7607 (calculated), relative error -0.7 ppm.
